A tray of foods demonstrating various vitamin-containing foods was shown, and these were contrasted with commercial vitamin preparations from the standpoint of relative cost, convenience of administration, and psychologic effect.

To sum up the normal diet a basal or foundation diet was described and demonstrated. The fundamentals of menu building were explained, and attention was drawn to the importance of adequate quantities of vitamins and of mineral salts. The students were asked to alter the basal diet in calories and bulk without changing the vitamin and mineral salt content. Adjustment of this menu for a person of slender build and also for one of stocky build showed clearly the fundamentals underlying the planning of diets for persons of different physical and constitutional types.¹

CALCULATION OF DIETS

The diabetic diet was used to illustrate the importance of quality and quantity of foods and to show methods of calculating diets. Emphasis was placed on the importance of planning a diabetic diet so that a minimum of insulin would be needed. The significance of the relative rates of absorption of carbohydrate from 5 to 10 per cent fruits and vegetables was discussed. It was demonstrated that the diabetic diet is apt to be low in vitamin B and that special provision must be made for its inclusion in the diet as prophylaxis against neuritis. It was stated that the content of vitamin B in the "normal diet" also is apt to be inadequate.

THERAPEUTIC DIETS AS MODIFICATIONS OF THE NORMAL DIET

Several sessions were devoted to the study of diet in disease. Attention was called to the fact that the terms nonresidue, liquid, soft, light, bland and general diet are not standard in all hospitals.

The normal diet was varied to meet the needs in specific diseases by altering (1) energy content, (2) consistency and residue, (3) amount of protein, fat and carbohydrate, (4) amount of the different mineral elements, (5) amount of the different vitamins, (6) water content and (7) acid-base balance. For each disease the students were asked to submit properly

calculated diets to demonstrate each type of alteration. The therapeutic indications for these altered diets were given in detail.

It was emphasized that it is the physician's duty to see that all special diets supply the necessary nutritional substances in adequate quantity so that states of malnutrition do not develop. If a special diet does not contain optimal quantities of vitamins, minerals and proteins, it is certain that a deficiency disease will develop. When it is necessary to put the patient on a highly restricted diet or a qualitatively deficient one, such a regimen should not be maintained for long.

HOW TO ORDER HOSPITAL DIETS

In teaching the students how to order hospital diets, the following instructions were given:

1. Learn what the patient would receive on the regular hospital menu before asking for a special diet.
2. Order diets by quantity of food elements (carbohydrate, fat, protein, minerals, vitamins and water) rather than by name (e. g., 'bland diet').
3. Do not make the diet unnecessarily restrictive.
4. Learn whether a patient is eating all the food on his tray before ordering interval feedings.
5. Before prescribing a weight-reducing or a weight-increasing diet, learn the previous caloric intake. By gradual increases or reductions in the quantity of food, psychologic or physical difficulties will be avoided.
6. Feel free to consult the dietitian in regard to all dietary problems. Through experience with patients and their problems, she is often able to give valuable suggestions and advice.

PROBLEMS CONCERNED WITH FORCING FLUIDS

Certain difficulties encountered in the forcing of fluids were considered. The palatability of flavored fluids in various illnesses was shown to be of importance. It was pointed out that a well person may enjoy any kind of fruit juices, whereas the sick person, especially if he is febrile, may rebel at the prospect of ingesting large quantities of these same fruit juices.

It was emphasized that, when large amounts of fluid are needed, a fluid without pronounced flavor and with a low sugar content is tolerated best. The students were allowed to taste various kinds of fruit juices and other beverages. The wide variation in cost of different drinks was shown. It was pointed out that colored fluids have more appeal for children than uncolored fluids.

DIETARY FADS

Dietary fads, and regimens fostered by so-called nutrition and health lecturers, were discussed in detail. Their influence in making many persons food conscious is evidenced by the increase in the number of "health-food" stores throughout the country. Although some good has been accomplished by the focusing of attention on the importance of diet in maintaining health, yet harm has often resulted from the unbalanced diets so often advised. Furthermore, the foods sold are in many cases unnecessarily expensive.

It was suggested that each student keep a file of diets sponsored by food faddists, so that he may have knowledge of and be able to discuss such diets with his patients.

SELECTION OF FOODS

The assignment of practical problems and the use of demonstrations in the teaching of dietetics and its relation to disease have obvious value from the standpoint of selection of foods. The writing of prescriptions and the observation of the diet prescribed make for evident

errors in knowledge and judgment. The following incidents illustrate the manner in which such errors were brought promptly to the attention of the students. On one occasion a bland diet prescribed by a student was found to include lettuce and tomato salad, the error was in part due to his fondness for this particular food. Another student who planned a low fat diet discovered, on demonstration, that his selection of food was most unappetizing. His comment was that the "diet looked much better in writing than the food did on the tray." But to the trained eye, the menu would not have looked appetizing even in writing! By means of such glaring errors as these, the students learned to appreciate the importance of careful selection of food from the standpoint of the patient whose appetite is not easily tempted.

DIETARY CONSULTATION

One important feature of the instruction was the provision of an expert dietitian to act as consultant in the outpatient department. The students were advised to confer with her on details of diet and to discuss with her the dietetic problems, both economic and physiologic, of their patients. By these means and by consultation with the hospital dietitian, close correlation between instruction and practical application was obtained.

SUMMARY

Our students were impressed with the importance of malnutrition as a cause of disease and with the significance of diet as a therapeutic agent in the prevention and treatment of disease. They were afforded an opportunity to review the physiology and biochemistry of digestion in the normal person and to learn of the alterations that occur in diseased persons. The application of diet to the treatment of specific diseases was shown. Demonstrations were given illustrating the importance of vitamins and minerals in the maintenance of good health. The problem of the subclinical vitamin deficiencies was discussed in detail.

By demonstrations, it was shown that palatability, proper combinations of food, attractiveness, service and cost of food are important considerations in the planning of diets.

The writing of dietary prescriptions by name was discouraged. By instruction in the principles of the science of nutrition, our students learned to write intelligent dietary prescriptions based on the broadest application of these principles.

University of California Hospital

Deaf-Mutes—According to Dr. Harold L. Pabcock, professor of otology at Boston University School of Medicine in a lecture April 5, at the university's school of education, there were 44,885 deaf-mutes in the United States, in 1937, or one to every 2,359 of the population. Two forms of deaf-mutism are recognized: the congenital and the acquired; the latter predominating in numbers by about two to one. The dominance of deaf-mutism is a family taint, and an individual coming from such a family may pass the defect on to his children although he himself is free from the disease. Children of normal mental development who lose their hearing after the age of 6 rarely become dumb. The most important single cause of acquired deaf-mutism is cerebrospinal meningitis; other infections that may cause it are scarlet fever, measles, diphtheria and mumps. As the outlook for the return of hearing, in both forms of deaf-mutism is practically hopeless, the problem of treatment resolves itself into a problem in education.

MEDICAL TREATMENT OF HYPERTHYROIDISM WITH A HIGH FAT DIET

SAMUEL SOSKIN, MD
ANDI A MIRSKY, MD
CHICAGO

The current surgical treatment of hyperthyroidism is attended by a high percentage of beneficial results and entails only a relatively short period of invalidism. This state of affairs, gratifying though it is, has left little or no opportunity for attempts at medical treatment in severe cases of the disease. A patient who absolutely refused to submit to surgical operation offered us such an opportunity. The results of medical treatment in her case were strikingly successful and warrant further trial of the form of therapy which we employed.

Bed rest and high caloric diets are useful adjuncts in the treatment of hyperthyroidism but are in themselves of very limited effect in severe cases. It is generally agreed that the use of iodine in severe hyperthyroidism is effective as a temporary, palliative measure but should be restricted to the preparation of the patient for surgical intervention. Our patient did not receive any iodine (except that which might have been incidentally present in the ordinary foodstuffs of her diet) either before or after she came under our care. The rationale of our treatment was based on previous experimental work demonstrating that the composition of the diet might influence the action of administered thyroxine or the course of a spontaneously occurring hyperthyroid state.

Abelin and his co-workers¹ have shown that rats fed on a diet of green vegetables and rich in minerals and vitamin A become resistant to the action of thyroid extract as judged by their storage of liver glycogen. Several subsequent clinical reports² have given evidence of moderate benefit obtained from the use of vitamin A, or fatty substances containing it, in cases of exophthalmic goiter. More recently Hoffman³ has demonstrated that the feeding of olive oil to thyroxine-treated mice will prevent the fall in serum lipase which would otherwise occur. These fat fed animals also survived longer than similarly thyroxinized control animals. Loumos⁴ has also demonstrated that the feeding of certain pure fats will cause rats to be resistant to administered thyroid substance as judged by weight loss. These results are consistent with the observations of Bodansky and Duff⁵ and of Danforth and Loumos⁶ on the decreased effectiveness of thyroid extract in pregnancy, in which condition the blood fats are apt to be increased. These experimental results suggested the possibility that the hypolipemia of hyperthyroidism might be more than a secondary or incidental effect of the disease. We therefore proceeded to treat our patient with a high fat diet.

REPORT OF CASE

History.—Mrs. R. J., a white woman, aged 36, a housewife, seen in the Mandel Clinic of the Michael Reese Hospital, presented the symptoms and signs of severe hyperthyroidism. It was the consensus of both the medical and the surgical members of the thyroid group that prompt subtotal thyroidectomy was indicated. When it became apparent that the patient was adamant in her refusal to submit to operation, she was offered and accepted the experimental form of therapy to be described.

July 11, 1935, the patient was admitted to the Max Pam Unit for Metabolic Research of the Michael Reese Hospital. There was nothing significant in the history prior to the onset of the present illness. The menses began at the age of 14, occurred regularly every twenty-eight days, lasted two days and were not painful. The patient had been married for nineteen years and had two children alive and well. There had been two induced miscarriages. She smoked little, took alcohol in moderate amounts and stated that she did not use drugs.

The onset of the present symptoms occurred four months prior to admission. The patient noticed nervousness and irritability, increased perspiration and tremor of the hands. These symptoms progressed and, in addition, there were increasingly frequent attacks of dull, aching, substernal pain. Physical exertion was accompanied by dyspnea and occasionally also by swelling of the ankles. During this period there was a loss of 14 pounds (6.4 Kg.).

Physical Examination.—The temperature was 98.6 F., pulse rate 116 per minute and respiratory rate 20 per minute, at rest in bed. The weight was 111½ pounds (50.5 Kg.). The skin

The plotted values for the basal metabolic rate, weight and blood cholesterol respectively represent average values for periods of two weeks from the time of admission to the hospital to the present. The vertical bars representing the blood cholesterol values indicate total cholesterol. The cross-hatched portion indicates cholesterol esters while the clear portion indicates the free cholesterol.

was flushed and the patient was perspiring freely. There was some increase in the width of the palpebral fissures but no exophthalmos. There was a definite lid lag but no other eye signs. The thyroid gland was diffusely enlarged and smooth in consistency. There were no abnormalities in the respiratory system or abdomen. The apex beat of the heart was diffuse. Percussion revealed the left cardiac border to be 10 cm. from the midsternal line. The rhythm was regular and there were no adventitious sounds. The blood pressure was 148 systolic, 74 diastolic. There was a fine tremor of the fingers. The deep reflexes were slightly hyperactive. Sensation was normal.

Laboratory Examination.—There was a faint trace of albumin in the urine; otherwise it was normal. Examination of the blood revealed red blood cells 4,200,000, hemoglobin 75 per cent (Sahli), white blood cells 5,900, neutrophils 65 per cent, lymphocytes 20 per cent and monocytes 15 per cent. Chemical examination of the blood revealed sugar 89 mg. per hundred cubic centimeters, total cholesterol 176 mg. and cholesterol esters 123 mg. An electrocardiogram showed slurring of the QRS complex in lead 3, negative ST in lead 2 and tall and sharply peaked T in lead 2. These appearances were interpreted as

suggestive of myocardial involvement July 13, the basal metabolic rate was +62.9 July 16, +53.3, July 19, +55.2

Progress—While in the Hospital For two weeks following her admission, while the control data were being obtained the patient was given a diet consisting of protein 80 Gm, fat 80 Gm and carbohydrates 400 Gm, total calories 2640

July 24 the diet was changed to protein 90 Gm, fat 230 Gm, carbohydrates 90 Gm, total calories 2790 For a period of twenty-three days (August 9 to September 2) 3 Gm daily of cholesterol was added to the diet by incorporating it in the butter ration Rest in bed was enforced No other form of therapy was employed at any time

There was a gradual regression of all symptoms and signs of hyperthyroidism from the time at which the high fat diet was started The addition of cholesterol to the diet had no apparent effect on the rate of improvement and was discontinued for this reason The attacks of substernal pain, which occurred almost daily at the time of admission became less frequent and did not recur after August 8 The patient was discharged from the hospital October 14 At that time the basal metabolic rate varied around +30, her blood pressure was 130 systolic, 80 diastolic, and her weight was 118 pounds (53.5 Kg.)

Since Discharge from the Hospital The patient has continued on the same high fat diet at home and has returned for observation once every week to date, with few exceptions At each visit she has been questioned as to recurrence of symptoms a basal metabolic determination has been made and blood has been drawn for estimation of cholesterol Other examinations have been made, but at less frequent intervals

Since about January 1936 the patient has presented no symptom, sign or laboratory evidence of hyperthyroidism, either residual or recurrent The accompanying chart graphically demonstrates the progressive changes in the basal metabolic rate body weight and blood cholesterol from the time of her admission to the hospital to the present

At present (October 1937) the patient feels perfectly well and is able to undertake as strenuous activity as any normal person Her basal metabolic rate has varied around ± 0 and her blood cholesterol has remained above 200 mg per hundred cubic centimeters for many months A recent electrocardiogram shows T in leads 1 and 3 smaller, in lead 3 now inverted and in lead 4 normal There was a left axis shift The interpretation was that the electrocardiogram was within normal limits

Her weight has remained constantly about 130 pounds (59 Kg.) and has not gone higher only because she has voluntarily reduced her total caloric intake in order to avoid overweight

SUMMARY

In the case here presented, of acute and severe hyperthyroidism, the attending physicians and the consulting surgeon were in complete agreement as to the necessity for prompt surgical intervention Because the patient absolutely refused to submit to thyroidectomy it was deemed justifiable to attempt to treat her by medical means The treatment, for reasons outlined, consisted of a high fat diet Iodine was not administered at any time On this treatment the patient made a striking and complete recovery, which has persisted for almost two years during which time she has been observed at weekly intervals

It should be clearly understood that we do not believe that this single case warrants the routine employment of our dietary treatment in patients who are willing to submit to the established surgical therapy It is possible that our patient might have recovered spontaneously under any expectant form of treatment Furthermore, the time required for our treatment even if ultimately proved to be generally effective, makes it economically less practical than the surgical method Nevertheless our results should serve to stimulate interest in the application of the more recent knowledge of thyroid physiology to the treatment of hyperthyroidism Meanwhile they suggest a mode of procedure which may be of value

in certain cases (such as ours) in which surgery is refused or in which the hazards of surgery are too great Since our opportunities for the further testing of this form of therapy are limited, we are reporting our experience in order that others may be able either to confirm or to deny its value, as opportunities present themselves

Twenty-Ninth Street and Ellis Avenue

THE RELATIONSHIP OF VITAMIN A TO THE HEALTH OF INFANTS

FURTHER OBSERVATIONS

J. M. LEWIS, MD

AND

L. H. BARENBERG, MD

NEW YORK

In previous communications¹ we stated that the average diet of artificially fed infants contains an adequate amount of vitamin A This contention was based on the fact that no improvement in the nutritional status or increase in the immunity to infections was brought about by adding large quantities of vitamin A in the form of cod liver oil, halibut liver oil or carotene (which contains the provitamin) to the diet employed in the Home for Hebrew Infants The diet used at this institution is similar to that which is generally prescribed in

TABLE 1—Approximate Number of International Units of Vitamin A in the Low and in the High Vitamin A Diet, as Compared with the Number in the Average Diet of Infants

| Age Months | Low Vitamin A Diet | High Vitamin A Diet | Average Diet |
|------------|--------------------|---------------------|--------------|
| 2 | 500 | 17,165 | 2,100 |
| 6 | 700 | 1,415 | 7,000 |
| 12 | 1,000 | 17,715 | 4,000 |

private practice by pediatricians and by general practitioners For example, from 1 to 2 ounces (30 to 60 cc) of milk is given per pound (453 Gm) of body weight, the amount depending on the age of the infant, orange juice is prescribed at the age of 6 weeks, cereal at 4 months, vegetables at 6 months, desserts at 8 months eggs at 10 months and meat at 1 year

Recently Mackay² carried out an investigation on the vitamin A requirement of infants in the outpatient department of a London hospital Sixty infants were given extra amounts of vitamin A, and fifty eight infants receiving the usual diet served as controls These infants were observed for an average period of eight months Mackay found that there was no difference in the morbidity or the mortality rate for the two groups of infants nor was there any distinction in the rate of growth However of sixty infants who received extra vitamin A sixteen, or 27 per cent, had some form of infective cutaneous lesion whereas of the fifty eight infants in the control group, thirty or fifty-two per cent, had cutaneous infections It should be mentioned, however that Mackay included as cutaneous infections such conditions as diaper rash and intertrigo She expressed

From the Home for Hebrew Infants.

2. Mackay, Helen M. M. Vitamin A Deficiency in Children. J. Child Health 9: 133 (June) 1934.

the opinion that infections of the skin are one of the earliest manifestations of vitamin A deficiency and that adding supplements of vitamin A to the diet of infants will diminish the incidence of these infections

On the other hand, Blackfan and Wolbach³ found that in thirteen infants suffering from vitamin A deficiency "infection of the skin, localized or general, was noticeable by its infrequency" This observation is of considerable importance because of the fact that six of these infants suffered from xerophthalmia, a manifestation of marked vitamin A deficiency All six infants had received a diet grossly inadequate in vitamin A Two received skimmed milk, two boiled condensed milk and one a preparation of soy bean flour (sabee), and the sixth could not swallow sufficient food on account of congenital malformations

The diagnosis of vitamin A deficiency in the case of six infants not exhibiting xerophthalmia, in Blackfan and Wolbach's study, was made post mortem when the characteristic histologic changes in the epithelial tissues were noted, metaplasia from columnar or cuboidal into keratinized stratified squamous epithelium Five of these infants had chronic generalized infections, and one had suffered from congenital malformation of the bile duct They had received a diet which included cod liver oil, in fact four of them were given cod liver oil with dilutions of cow's milk for a considerable period while at the hospital It seems apparent, therefore, that the development of vitamin A deficiency in this group of infants cannot be accounted for by an inadequacy of vitamin A in their diet but was due, as the authors stated, "to grave metabolic disturbances interfering with proper absorption, storage and utilization of vitamin A or its precursor, carotin" The state of nutrition was estimated in twelve of the cases of vitamin A deficiency reported by Blackfan and Wolbach All of the infants were undernourished, seven were from 20 to 40 per cent below normal weight, three were from 40 to 60 per cent below the average and two were 62 and 68 per cent, respectively, below the average Twelve of the thirteen patients showed evidences of infection of the respiratory tract, and in nine instances involvement of the respiratory system consisted of a generalized infiltration of the lungs

TABLE 2—Incidence and Severity of Infections of the Respiratory Tract in the Two Groups

| Groups | Number of Infants | Average Age at Beginning of Study, Mo | Average Period of Observation, Mo | Total Number of Infections | Infections per Infant | Severity | | |
|----------------------------|-------------------|---------------------------------------|-----------------------------------|----------------------------|-----------------------|----------|------------|----------|
| | | | | | | Mild % | Moderate % | Severe % |
| Small amount of vitamin A | 31 | 3.1 | 6.8 | 1* | 3.2 | 64 | 22 | 14 |
| Large amounts of vitamin A | 33 | 3.2 | 6.8 | 144 | 4.4 | 61 | 15 | 24 |

In view of the fact that many physicians rely on vitamin D milks or viosterol for the prevention of rickets in infants and therefore do not prescribe cod liver oil or other antirachitic preparations containing vitamin A, the question arose as to the margin of safety with respect to vitamin A in the average diet of infants Is the diet barely adequate in vitamin A or is the vitamin A content so excessive as to insure a wide margin of safety? Previous studies as already mentioned have indicated that the average diet is adequate in vitamin A

but have given little information⁴ as to the "degree of adequacy" If the average diet is on the borderline as to adequacy of vitamin A it would seem advisable to supplement it with preparations containing the vitamin The addition of such products would be necessary especially for those infants who fail to take the whole amount of their prescribed diet If, on the other hand,

TABLE 3—Incidence and Severity of Infections According to Age During Administration of Low and of High Vitamin Diet

(Average period of observation, 6.8 months)

| Age at Beginning of Study, Mo | Vitamin A Diet | Number of Infants | Total Number of Infections | Severity | | | Infections per Infant |
|-------------------------------|----------------|-------------------|----------------------------|----------|----------|--------|-----------------------|
| | | | | Mild | Moderate | Severe | |
| 0-3 | Low | 11 | 21 | 17 | 2 | 2 | 1.9 |
| | High | 10 | 27 | 21 | 2 | 4 | 2.7 |
| 3-6 | Low | 26 | 68 | 46 | 11 | 7 | 2.6 |
| | High | 26 | 63 | 38 | 10 | 17 | 2.5 |
| 6-9 | Low | 14 | 44 | 32 | 12 | 10 | 3.1 |
| | High | 17 | 52 | 29 | 9 | 14 | 3.1 |

a considerable reduction in the vitamin A content of the average diet has no deleterious effect it would seem superfluous to add extra amounts of vitamin A

In order to obtain information on the margin of safety with respect to vitamin A in the average diet of infants, it was decided to follow the course of a group of infants receiving a diet which contained considerably less vitamin A than does the average diet It was also planned to observe simultaneously another group of infants receiving a diet which contained an excessive amount of vitamin A and to compare the two groups of infants as to state of nutrition and resistance to infections This study was carried out from November 1934 to June 1935 and from November 1935 to June 1936

The diet low in vitamin A consisted of a dry preparation of milk which was partly skimmed (dryco) and which, when reconstituted to its original volume, contained 1.5 per cent fat The vitamin A content of this milk was approximately 650 international units per quart of reconstituted milk,⁵ as compared with an average of 2,775 international units in a quart of whole milk⁶ Orange juice was given at the age of 6 weeks, cereal at 4 months and vegetables at 6 months Spinach and carrots, as well as butter and egg yolk, were excluded from the diet because of their high vitamin A content Fifteen drops of viosterol were given daily It will be noted in table 1 that infants aged 3 months received an average of approximately 500 international units of vitamin A, infants aged 6 months 750 units and those aged 12 months 1,050 units This diet contained as may be noted in table 1, about one fourth of the vitamin A content of the average diet of infants

The infants on the high vitamin A diet were given the same foods as those on the low vitamin A regimen, but their diet was rendered high in vitamin A by the addition of fifteen drops of halibut liver oil⁷ containing 16,665 international units of vitamin A Infants aged 3 months, 6 months and 12 months given the high vitamin A diet received an average of approximately 17,165, 17,415 and 17,715 international units of vitamin A,

4 In one of our previous papers¹ we recorded our observations on nineteen infants who received a low vitamin A diet However because of the limited number of infants one could not draw any definite conclusions from the observations

5 Personal communication to the author from Dr George Supplee research director of the Dry Milk Company

6 Sherman H C Chemistry of Food and Nutrition New York: Macmillan Company 1937

7 Halibut liver oil combined with viosterol was supplied by Mead Johnson & Co

Blackfan K D and Wolbach S B Vitamin A Deficiency in Infant J Pediatr 1: 679 (Nov) 1935

respectively. These infants therefore received from seventeen to thirty-four times as many units of vitamin A as the infants receiving the low vitamin A diet. As will be noted in table 1, the vitamin A content of this diet contained from four to eight times as much vitamin A as the average diet.

Fifty-one infants ranging in age from 3 weeks to 9 months were given the low vitamin A diet, and fifty-three infants of the same age group received the high vitamin A diet. The average age of the two groups at the beginning of the study, as may be noted in table 2, was comparable, the former group having an average age of 5.1 months and the latter an average age of 5.2 months. The infants received these diets for an average period of six and eight-tenths months, so that the average age at the end of the period of observation was about 12 months. The infants in the two groups were housed in the same wards, and therefore external conditions, such as exposure to infections, nursing care and hygiene, were identical. Temperatures and weights were taken daily. Whenever the temperature rose above 100 F a careful physical examination was carried out. Infections were classified as mild, moderate and severe, depending on the nature and the duration of the illness. Purulent otitis media, mastoiditis and pneumonia were considered severe infections. Complete physical examinations were made at monthly intervals.

A glance at table 2 reveals that the fifty-one infants receiving small amounts of vitamin A had 133 infections during the course of the investigation, an incidence of 2.6 infections per infant. The fifty-three infants receiving large amounts of vitamin A in their diet had 144 infections, an incidence of 2.7 infections per infant. Of the infections in the group receiving the low vitamin A diet, 64 per cent were classified as mild, 22 per cent as moderate and 14 per cent as severe, whereas, of those in the group receiving the high vitamin A diet, 61 per cent were mild, 15 per cent moderate and 24 per cent severe. Thus there was no significant difference between the two groups as to the incidence and the severity of infections of the respiratory tract.

In table 3 the incidence and the severity of infections of the respiratory tract are recorded in relation to age

tract would be manifested at a later age. It will be observed, however, in table 4 that there was no difference as to incidence or severity of infections between the two groups for seven months after the discontinuance of the special diets.

At this point it should be mentioned that Clausen⁸ expressed the opinion that a diet containing adequate amounts of vitamin A in early months of life may

TABLE 5—*Gain in Weight in the Two Groups*

| Age, Months | Average Gain per Month, Ounces | |
|-------------|--------------------------------|---------------------|
| | Low Vitamin A Diet | High Vitamin A Diet |
| 0-3 | 2.8 | 0.0 |
| 3-6 | 24.9 | 24 |
| 6-9 | 1.6 | 1.1 |
| 9-12 | 9.5 | 0 |

decrease the severity of infections during the latter part of the first year and during the second year. However, according to the data in tables 3 and 4, infants who received large amounts of vitamin A during the first few months of life were no less susceptible to severe infections during the second half of the first year and during the early part of the second year than those who had not received supplements of vitamin A during their first few months of life.

A comparison of the gain in weight between the two groups of infants is recorded in table 5. It will be observed that infants receiving small amounts of vitamin A gained just as well as infants receiving large amounts of the vitamin. It may be added that there was no difference as to rate of growth in length between the two groups.

Not only was no distinction discernible in the nutritional status and the resistance to infections of the respiratory tract of the two groups of infants, but there was no perceptible difference in the incidence of cutaneous infections, conjunctivitis and vaginitis. Since the appearance of cornified epithelial cells in the vaginal secretions is the earliest sign of vitamin A deficiency in the rat according to Evans,⁹ we examined vaginal smears and as suggested by Blackfin and Wolbach scrapings from the conjunctiva, the mouth and the nose, of a number of the infants who received the low vitamin A diet. The results of these examinations were, however, negative.¹⁰

COMMENT

This investigation revealed that the health of a group of infants receiving one-fourth the amount of vitamin A present in the average diet was just as good as the health of a group of infants receiving from seventeen to thirty-four times as many units of vitamin A. The low vitamin A diet contained therefore, an amount of vitamin A which was above the minimum requirement as judged by the nutritional state of the infants and their resistance to infections. Thus it would seem that the average diet contains at least four times as many vitamin A units as the minimum requirement.

9. Evans, H. M. *J. Biol. Chem.* 77: 651 (May) 1923.

10. Since the completion of this study we have had the opportunity of observing the effect of the special diets on a pair of apparently identical female twins. The infants were admitted to the institution at 3 months of age and were given formulas containing dilutions of whole milk and 2½ months of age at which time one twin was placed on the low vitamin A diet and the other on the high vitamin A diet. They have received the special diets for four months and during this time no difference between the twins has been noted as to incidence of respiratory infections, rate of growth in weight and in length, and in hemoglobin content of blood. Repeated examination of the urine, vaginal smears and scrapings from the mucous membrane of the nose, mouth and conjunctiva in the two infants did not reveal any difference in the epithelial cells of the conjunctival cells.

TABLE 4—*Incidence and Severity of Infections for Seven Months After Administration of the Special Diets Has Discontinued*

| Age at Beginning of Study, Mo. | Vitamin A Diet | Number of Infants | Total Number of Infections | Severity | | Infections per Infant |
|--------------------------------|----------------|-------------------|----------------------------|----------|--------|-----------------------|
| | | | | Mild | Severe | |
| 0-3 | Low | 11 | 16 | 10 | 4 | 1.5 |
| | High | 10 | 22 | 12 | 3 | 2.2 |
| 3-6 | Low | 26 | 19 | 11 | 4 | 0.7 |
| | High | 26 | 2 | 15 | 5 | 0.1 |
| 6-9 | Low | 14 | 9 | 5 | 2 | 0.6 |
| | High | 17 | 18 | 9 | 2 | 1.1 |

at which the special diets were begun. We collected these data in order to find out whether there was any difference in susceptibility to infections of the respiratory tract between the two groups of infants at the various age levels. It will be noted that, irrespective of the age at which administration of the special diets was begun, there was no significant difference as to incidence and severity of infections between the infants receiving large amounts of vitamin A and those receiving small amounts.

Both groups of infants were observed for seven months after administration of the special diets was discontinued, we wished to determine whether any differences in susceptibility to infections of the respiratory

How many units of vitamin A represent the minimum requirement for infants is not known. As a result of experiments on rats, cattle, sheep and swine, Guilbert¹⁰ stated that mammals require approximately 72 international units (29 micrograms) of vitamin A per kilogram of body weight to prevent the development of vitamin A deficiency. If this generalization is applied to infants, the minimum requirement of vitamin A for a 3 month old infant weighing 6 Kg would be about 432 units for a 6 month old infant weighing 8 Kg 576 units and for a 12 month old infant weighing 10 Kg 720 units. Table 1 shows that these estimates are below the vitamin A content of the low vitamin A diet which we employed. Calculation of the vitamin A content of the average diet reveals that it contains from five to six times the minimum requirement as postulated by Guilbert.

One of the earliest signs of vitamin A deficiency in children and in adults, as well as in cattle, is night blindness, or poor dark adaptation. Jeans and his co-workers¹¹ reported that of the thirty-seven children from 7 to 10 years of age examined with a special photometer, seven had poor dark adaptation and were therefore suffering from vitamin A deficiency. These investigators gave 3,000 units of vitamin A to a child 11 years of age who had poor dark adaptation, and after two months the photometric tests were approximately normal. Another child 11 years of age, who had normal dark adaptation, was given 3,000 units of vitamin A for three months, during which time the photometric tests continued to be normal. For these two children, according to Jeans, 3,000 units seemed to meet the vitamin A requirements as judged by the special test for dark adaptation. Jeghers,¹² who studied the prevalence of night blindness among adults, concluded that 4,000 units of vitamin A daily represents the minimum requirement for adults and recommended 6,000 units daily to secure optimal effects in regard to dark adaptation. The experiences of Jeans and Jeghers with human beings are in agreement with the hypothesis of Guilbert that the requirement of vitamin A, in contradistinction to that of vitamin D, depends on body weight rather than on rate of growth. Thus adults required many more units of vitamin A than did children to protect them against night blindness. Similarly, it would seem probable that children require a greater number of vitamin A units than do infants to permit normal dark adaptation.

The difficulty of performing photometric tests for dark adaptation on infants is obvious, although a procedure for this purpose has recently been suggested by Friderichsen and Edmund.¹³ Their method of testing the visual acuity of infants in the dark requires a great deal of patience and judgment on the part of the examiners, and it will be of interest to see whether it can be put to practical use in other clinics. It is possible that by means of this test the minimum requirement of vitamin A for infants will be ascertained.

SUMMARY

In order to obtain information on the margin of safety with respect to the vitamin A content in the

average diet of infants, fifty-one infants were given a diet which contained approximately one-fourth the vitamin A content of the average diet and fifty-three infants were given a diet which contained from four to eight times the number of vitamin A units in the average diet. These infants were observed for an average period of six and eight-tenths months, and a comparison of the nutritional status and the incidence of infection of the two groups was made. The results showed that there was no difference as to nutritional state or as to susceptibility to infection between the two groups of infants. It would seem therefore that the average diet of infants contains at least four times as many units as the minimum requirement, as judged by the nutritional state of infants and their resistance to infections.

Clinical Notes, Suggestions and New Instruments

A NEW TYPE WALKING IRON

HOWARD E. SNYDER, M.D., WINFIELD, KAN.

R. A. Griswold¹ of Louisville used a skate type walking iron in the ambulatory treatment of fractures of the lower extremity in the fracture service at Louisville City Hospital in 1934 and 1935. It proved satisfactory but was discontinued because each iron had to be made to the individual pattern.

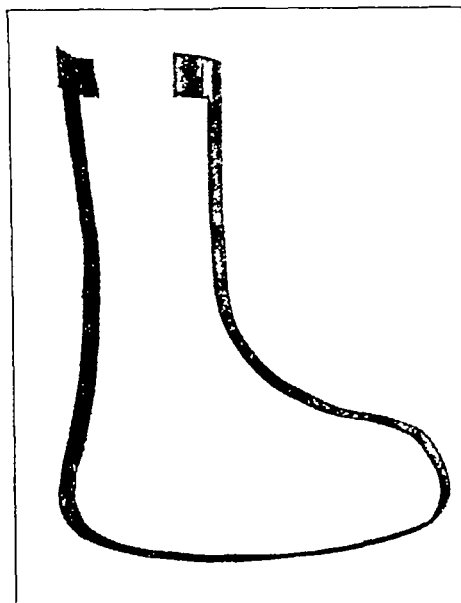

Fig. 1.—The walking iron made of spring steel 1 inch wide and one eighth inch thick.

This necessarily added to the expense. It was also difficult to have the irons properly made and applied when interns or residents were responsible for the task.

In October 1936 the principle of this skate type iron was used in treating a patient with a fracture dislocation of the left ankle and a fracture of the shaft of the right tibia. From the experience gained with this case a new iron has been developed.

The iron is made of spring steel 1 inch wide and one eighth inch thick and extends down the back of the leg under the foot and back up the dorsum of the foot and front of the leg. A pattern is drawn in each case, the contour of the plaster cast

being accurately traced except on the plantar surface of the foot and dorsal surface of the toes. Here the iron is made to extend from 1 to 1½ inches below the heel and then gradually to curve upward so as just to touch the plantar surface of the cast at the toes. It then circles above the toes and again touches the plaster cast about 1 inch proximal to the web of the toes. The vertical arms extend half way up the leg. The pattern is delivered to the welder, and the iron is usually available in one or two hours.

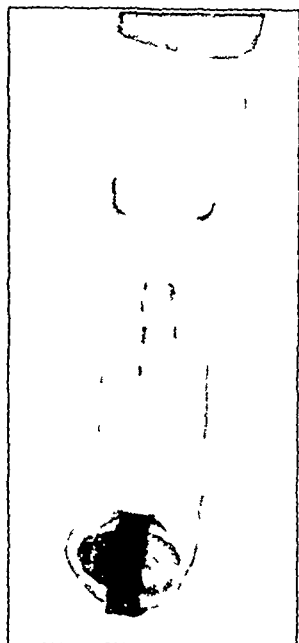

Fig. 2—Front view of cast with walking iron applied

This type iron has been used for twelve patients with fracture dislocation at the ankle, four patients with fractures of the tibia or both bones of the leg and two patients with fractures of the femur. The two patients with fracture of the femur and two of the patients with fractures of the leg bones had skeletal fixation by Steinmann pins incorporated in the unpadded plaster cast.

The advantages of this walking iron are that

1 It permits a rocking motion of the foot and leg which closely simulates the normal gait

2 The patient does not tend to twist or rotate the leg externally with each step as when the stirrup type iron is used

3 The patient is able to move faster and with more comfort

4 All the plaster on the foot is protected by the iron and hence does not break or wear out with walking

The disadvantages are that

1 The iron must be made after an individual pattern

2 The expense is increased

3 There may be some delay in applying the iron

However, the iron can be made by almost any welding or blacksmith shop and in a short time. It has been my custom to wait from twelve to twenty-four hours after applying the cast to bind on the walking iron, to avoid denting the soft plaster in applying the iron.

A walking iron should be used only on unpadded plaster casts. No one should attempt to apply it unless he is thoroughly familiar with the technic of application and with the inherent dangers of the unpadded plaster cast. This subject has been well covered by Boehler² and by Griswold.³

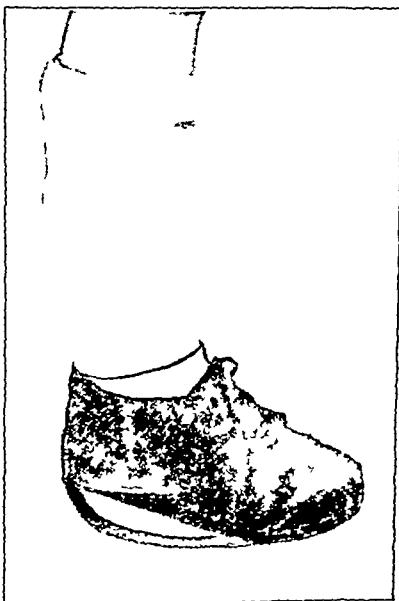

Fig. 3—Lateral view showing a protective leather boot which laces over the dorsum of the foot and also behind the heel. Note the curve of the iron from heel to toe.

GONORRHEAL WOUND INFECTION FOLLOWING SIMPLE APPENDECTOMY

S. J. SULLIVAN, M.D., CHICAGO

Because of renewed general interest in venereal infections and the exceptional rarity of reported venereal wound infection, I am offering this report. An examination of the literature does not reveal a single case of a pure gonorrheal infection of an abdominal incision. Many cases of skin manifestations of gonorrhea have been reported, but living gonococci in the fatty tissues are undoubtedly rare.

REPORT OF CASE

A married woman, aged 44, the mother of three grown children, was seen early in the morning of Sept. 15, 1937, with all the typical symptoms and signs of an acute appendicitis. She was hospitalized at once and a count of 20,700 white blood cells of which 97 per cent were polymorphonuclears, was obtained. Immediate operation was agreed on and the patient was prepared. Owing to the typical history and physical signs of acute appendicitis and a negative bimanual vaginal examination a right rectus incision was made. When the peritoneum was opened about a drachm (4 cc.) of grayish serous fluid escaped. The appendix was brought into the wound and substantiated the preoperative diagnosis. It was removed with ease, and the stump was inverted. The laboratory reported an acute suppurative appendicitis.

Exploration of the abdominal cavity revealed light adhesions in the region of the gallbladder. These were freed blindly. The uterus was normal and the tubes were only slightly inflamed and not enlarged. Neither was stripped down for pus. The ileum, however, was examined carefully for 8 or 10 feet and presented many small petechial hemorrhagic areas the size of a pinhead. There were none of these on the appendix. This unusual finding prompted me to take a culture on blood agar medium. The wound was then closed in layers and without drainage. Saline solution was given subcutaneously throughout the operation.

Because of the hemorrhagic ileum and the possibility of a hemolytic streptococcus infection, an order was given for 25 cc. of protosil¹ to be administered at once when the patient left the operating room, to be repeated in eight hours. However, the culture taken at operation later proved to be negative.

For the next three days the patient was quite uncomfortable with nausea, vomiting and generalized pain in the abdomen, and it was necessary to use the Levine apparatus, intravenous dextrose and several doses of narcotics. During this time, however, the white count fell from 20,700 before operation to 11,500 on the following day, 10,500 on the second and 9,500 on the third postoperative day.

The wound was examined on the fifth day but did not appear to be healing properly, although there was no discharge on the dressing. On the seventh day the patient was feeling very well and had an excellent appetite eating a general selective diet. The sutures were then removed, and before butterfly adhesive strips were applied the wound started to open and discharge a clear grayish serous fluid. A smear was made of this fluid and was reported to be gram negative intracellular diplococci with the outline of gonococci.

The following day a culture was taken on ascitic medium; it showed no growth but four more direct smears all revealed gram negative diplococci. On the ninth day another culture on ascitic medium showed an abundant growth of definite gonococci which had lived and grown in the fatty tissues between the skin and the anterior rectus muscle fascia. The wound was left tightly strapped with adhesive strips and the patient left the hospital on the fourteenth day. On the eighteenth day the adhesive strips were removed. The wound had healed perfectly. The patient was up and about the house. Antigonorrheal treatment is now in progress.

When the patient left the hospital a true history revealed that the patient's husband had been exposed to a venereal infection.

three days before she had intercourse with him, and on the day she entered the hospital he noticed that a discharge developed which proved to be gonorrhea. This was seven days after his exposure. Both the patient and her husband stated that there had been no previous venereal involvement, and serologic reactions were negative.

It is interesting to note the rapid spread of a gonococcal infection from the vagina to the peritoneum in four days also to note petechial hemorrhagic areas produced undoubtedly by gonococci.

2630 East Seventy-Fifth Street

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING MINUTES AND APPRECIATION
H. A. CARTER Secretary

ABSTRACT OF MINUTES, THIRTEENTH ANNUAL MEETING, COUNCIL ON PHYSICAL THERAPY, JAN 14-15, 1938

The Council on Physical Therapy held its annual meeting Jan 14 and 15 1938, at the headquarters of the American Medical Association in Chicago. Members who were present included Drs J. S. Coulter, A. U. Desjardins, H. T. Karsner, F. H. Krusen, H. E. Mock, F. R. Ober, Ralph Pemberton, H. B. Williams, Olin West, Morris Fishbein and Mr. Carter. Drs W. W. Coblentz, F. D. Dickson and W. E. Garrey were unable to attend the meeting.

Dr. Mock was reelected chairman and Dr. W. E. Garrey vice chairman. During the past year Dr. George C. Andrews resigned because he was obliged to curtail his activities. Since the annual meeting the Board of Trustees has appointed Dr. Anthony C. Cipollaro to fill the place made vacant by Dr. Andrews' resignation.

COMMITTEE ON RESEARCH

Five individuals in the course of the year who presented problems of merit, were awarded grants in aid of research. A number of articles were published in this period by past recipients of similar grants.

In reviewing the status of ultraviolet therapy, the Council recommended careful study to establish the exact role ultraviolet radiation plays in antirachitic activity and bactericidal action. The problem of comparing the antirachitic effect of ultraviolet radiation with that produced by drugs and fortified foods of known vitamin D unitage (or potency) was given consideration.

AUDIOMETERS AND HEARING AIDS

One accomplishment of the Council in the course of the past year was reported by the chairman of the Consultants on Audiometers and Hearing Aids¹ of the Council on Physical Therapy. Tentative Minimum Requirements for Acceptable Audiometers have been established adopted and published. The hope was expressed that a definite advance will occur in the fitting of hearing aids by utilizing the auditory chart readings. A report was made on a joint meeting of the Consultants on Audiometers and Hearing Aids and representatives of leading manufacturers of audiometers and hearing aid equipment. At this meeting many problems were ironed out and the cooperation led to the establishment of minimum requirements for acceptable audiometers. In reaching this solution, the American Standards Association cooperated. Representatives of the Council were sent to the Bureau of Standards in an effort to call forcibly to the attention of those interested in sound the urgent necessity for adopting an artificial ear for standardization of both audiometers and hearing aids. The consultants expressed the hope that in the future hearing aids may be

prescribed as accurately for individual hearing defects as eye glasses are now prescribed for the eye defects. It was pointed out, however, that this achievement is still far from being realized.

SURVEY OF LITERATURE

The Council voted that a plan be developed for presenting an annual survey of the literature on physical therapeutic subjects. This would entail abstracting current literature, limiting it to English publications.

ARTIFICIAL LIMBS

The Council voted to include artificial limbs in its list of devices eligible for consideration. An attempt will be made to establish standards in this field. A meeting is contemplated for the representatives of manufacturers of artificial limbs and consultants appointed by the Council. It was suggested that this meeting might well be conducted much like the joint meeting between the representatives of manufacturers of audiometers and hearing aids and the Consultants on Otology (cooperating with the Council).

ROENTGEN-RAY APPARATUS

Consideration of roentgen-ray apparatus was discussed at the meeting. The Council voted that a survey be made among groups interested in this field to determine a suitable approach and procedure for investigating such apparatus.

LOW VOLTAGE MACHINES

It was voted that the Council proceed with an investigation of low voltage machines, basing its decision on the contents of the adopted article "The Interrupted Low Frequency and Constant Electric Current in Medicine."

HIGH FREQUENCY ELECTRIC CURRENT

A method is being sought for testing the efficiency of short wave diathermy machines to take the place of the surgical procedure now employed, i. e., insertion of thermocouples into the living human thigh to measure the temperature rise. Several processes were suggested for example, the calorimeter, the photoelectric wattmeter and variations of these two. However, objections were raised against them and it was decided to investigate the problem further and attempt to devise a substitute method. It was pointed out that animals cannot serve as suitable test subjects for the thermocouple experiments because dosage depends on the expressed tolerance of the patient. At present there is no objective way of determining dosage with short wave units.

After careful consideration the Council voted to reaffirm its previous stand with regard to fever therapy—that manufacturers of short wave diathermy equipment wishing to promote their units for hyperpyrexia are expected to submit for consideration and acceptance the accessory equipment employed for maintaining fever temperature.

RADIO COMMUNICATION

Interference with radio communications by short wave diathermy units came up for consideration. The Council is of the opinion that restrictions of diathermy equipment to certain selected wavelengths would involve a serious handicap to research and practice in the therapeutic field. The Council believed that, if certain wavelengths were reserved for medical purposes only, the privilege of screening and filtering their installations should also be given to users of short wave equipment not on the reserved frequencies. The entire field of short wave diathermy has not been completely explored and it would be a serious drawback to restrict physicians to selected and specific wavelengths.

PUBLICATIONS

Since the supply of the second edition of the Handbook of Physical Therapy (5000 copies) is exhausted the Council voted to go forward with the revision of the entire book and have a third edition ready for distribution by June if possible. The Council also voted to revise the booklet Apparatus Accepted by the Council on Physical Therapy. This booklet will be ready shortly.

¹ Drs. George M. Coates, Lee W. Dean, E. P. Fowler, Austin A. Hayden, Isaac H. Jones, Douglas Macfarlan, Horace Newhart, Burt R. Shurly and William P. Wherry.

EDUCATIONAL ACTIVITIES

One of the most important educational features of the Council on Physical Therapy is the publication from time to time of reports on apparatus. However, there was a feeling among the members that the Council has identified itself too prominently with the consideration of apparatus and has placed too little emphasis on the practice of physical therapy not associated with machines and appliances. The time has come, in the opinion of the Council, to stress more and more the value of simple physical measures used in conjunction with medicine and surgery. It was the members' opinion that a long range policy might well be formulated and information of value made available to schools of medicine and the practicing physician. Although many universities have established physical therapy departments and are offering courses in physical therapeutics to the undergraduate students, it was felt that many more universities might well follow the same course. One of the best ways to establish a course in physical therapy in a medical curriculum is to have one physician placed in charge of the department and make him responsible for the instruction in the medical school. Some schools have selected young physicians from their ranks and sent them away for special training. These men returned later and were put in charge of developing physical therapy in their particular schools and connected hospitals.

The practicing profession is best reached through exhibits, films, publications, and lectures given by specialists in physical therapy. Just now two new films are being prepared, "Occupational Therapy" and "Aids in Muscle Training," for loan to the medical profession. The Council recommended publication of a number of reports dealing with definite results achieved by means of physical therapy, also preparation of articles to be published in magazines appealing to the layman. An exhibit was suggested for the American Medical Association meeting in San Francisco next June which will indicate, in a graphic way, to the medical profession, hospital directors and deans of medical schools what is being done in physical therapy.

The Consultants on Education² have been instrumental in promoting sound physical therapy in their respective communities by (1) arranging programs for state, county and other medical meetings, (2) holding clinics on various applications of physical therapy and (3) advising on educational matters, both graduate and undergraduate.

COMMITTEE ON STANDARDIZATION OF INSTRUMENTS
AND DRUGS

The Committee on Standardization of Instruments and Drugs³ of the American Medical Association was extended a vote of thanks for its splendid work in furthering the Council's interests.

AN APPRECIATION

The Council on Physical Therapy is very grateful to the following consultants who have given their time and effort freely toward furthering the work of the Council both in the investigation of apparatus and in advising on other problems.

Drs. Fred L. Adair, Francis Heed, Adler, M. Herbert, Barker, William Bierman, Simon Benson, Walter Boothby, Joseph Brenemann, C. C. Bunch, George M. Coates, L. F. Curtiss, Alex. Day, L. W. Dean, Geza de Takats, F. H. Everhardt, Bernard Fantus, Samuel Feinberg, George K. Fenn, E. P. Fowler, Jonas Friedenwald, Sanford Gifford, Harry Goldblatt, F. B. Gordon, Henry Hartig, Austin A. Hayden, Allan Hemingway, J. S. Hibben, Isaac H. Jones, Louis Katz, Disraeli Kobak, A. J. Kotkis, Richard Kovacs, Henry Laurens, Franklin P. Lowry, Douglas Macfarlan, George Miller, MacKee, John MacNie, Albert Miller, C. O. Molander, J. L. Myers, Tell Nelson, Horace Newhart, E. A. Oliver, S. L. Osborne, George Pfahler, Scott Reger, William Schmidt, B. R. Shurly, E. M. Smith, Jr., K. W. Stenstrom, Ivan B. Taylor, Clifford B. Walker, Grant E. Ward, Ralph Waters, Francis Carter Wood and William P. Wherry.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS FORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

STAPHYLOCOCCUS TOXOID (See New and Nonofficial Remedies, 1937, p. 405)

Parke, Davis & Co., Detroit

Staphylococcus Toxoid P. D. & Co.—A detoxified staphylococcus toxin prepared by treatment of the toxin with a 0.3 per cent formaldehyde solution at 37° C. The detoxification procedure is carried to such a degree that the first strength product will stimulate the production of 2½ international units per cubic centimeter of staphylococcus antitoxin in the blood of rabbits treated according to the method approved by the National Institute of Health. The second strength staphylococcus toxoid will stimulate the production of 5 international units per cubic centimeter of staphylococcus antitoxin in the blood of rabbits treated in the same way. The material is preserved with 0.01 per cent of merthiolate (sodium ethylmercuri thiosalicylate) and the usual sterility tests required by the National Institute of Health are made. Staphylococcus toxoid is tested for dermonecrotic and lethal innocuity according to methods outlined by the National Institute of Health. Each of the two strengths is marketed in 5 cc. rubber diaphragm stoppered bottles.

Dosage—The initial dose should range from 0.1 to 0.2 cc. (preferably the smaller dose) of the first strength product. Subsequent doses should be increased very gradually at intervals of from three to seven days depending on the local reaction and systemic response of the patient. After treatment has been increased to 1 cc. of the first strength the second strength product may be used, starting with a 0.1 to 0.2 cc. dose. Injections are made subcutaneously.

DILAUDID HYDROCHLORIDE (See New and Nonofficial Remedies, 1937, p. 305)

The following dosage forms have been accepted:

Hypodermic Tablets Dilaudid Hydrochloride 1 mg. (1/16 grain)
Hypodermic Tablets Dilaudid Hydrochloride 1 1/2 mg. (1/8 grain)

VIOSTEROL IN OIL (See New and Nonofficial Remedies, 1937, p. 473)

I. V. C. Viosterol (A. R. P. I. Process) in Oil—A brand of viosterol in oil—N. N. R.

Manufactured by the American Research Products, Inc., a subsidiary of General Mills, Inc., Minneapolis (International Vitamin Corporation, Inc., New York distributor). U. S. patent applied for trademark 314,818.

I. V. C. Viosterol (A. R. P. I. Process) in oil is prepared by the activation of purified ergosterol by low velocity electrons. The activated ergosterol is refined and dissolved in vegetable oil. The final product when assayed according to the U. S. P. method has not less than the vitamin D potency of viosterol in oil N. N. R.

Council on Foods

THE COUNCIL ON FOODS HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
FRANKLIN C. BING, Secretary

VEGETIZED MACARONI NOT ELIGIBLE FOR LIST OF ACCEPTED FOODS

Vegetized Macaroni made from a mixture of flour, water and powdered vegetables was submitted by the Golden Gate Macaroni Company, Incorporated, San Francisco, for consideration by the Council on Foods. The firm was advised that it would be necessary to provide information relative to the preparation and composition of the dried vegetables used in the product, their freedom from spray residues, and so on before consideration could proceed. The company expressed its willingness to comply with this requirement of the Council. Later the firm informed the Council that it would be impossible to provide the desired information because the Burbank Corporation, which produced the powdered vegetables, was unwilling to disclose any facts regarding the preparation of its product. The Council is of the opinion that the public deserves to know the ingredients of the foods it purchases. There are no arguments justifying secrecy about the composition of food. In view of this policy of the Council, Golden Gate Vegetized Macaroni is being listed among the food not eligible for acceptance.

MEDICAL LICENSURE STATISTICS FOR 1937

ANNUAL PRESENTATION OF LICENSURE STATISTICS BY THE COUNCIL ON MEDICAL
EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

For the thirty-sixth consecutive year the Council on Medical Education and Hospitals presents statistics of medical licensure. The report covers the year 1937 and deals with statistics regarding (a) medical licensing boards of the United States, the District of Columbia, the territories and the possessions of the United States, (b) boards of examiners in the basic sciences and (c) the National Board of Medical Examiners.

Official reports have been contributed by the medical licensing boards of all states, the District of Columbia, Alaska, the Canal Zone, Hawaii, Puerto Rico and the Virgin Islands, the homeopathic boards of Arkansas, Connecticut, Delaware, Louisiana and Maryland, the eclectic examining board in Arkansas, the twelve basic science boards in operation (Arizona, Arkansas, Colorado, Connecticut, District of Columbia, Iowa, Minnesota, Nebraska, Oklahoma, Oregon, Washington and Wisconsin) and the National Board of Medical Examiners. The homeopathic boards of Arkansas and Louisiana did not license any one during the year. Likewise no physicians were licensed in the Canal Zone.

The cooperation of the officers of the boards in supplying complete reports has made possible this annual compilation.

Reports of all examinations and those licensed by endorsement of credentials are carefully compared with the lists of graduates furnished by medical school officials so that errors in names of candidates, the medical school or the years of graduation are promptly corrected. In the occasional instance in which the applicant, according to the records, has not graduated or there is a record of irregularity, the state board is promptly notified. Credentials of physicians coming from abroad are verified by direct correspondence with the foreign medical school. The statements regarding the medical education and licensure therefore of all physicians are accurate.

The data were also entered in the biographic file of physicians and others maintained by the Directory Department of the American Medical Association, thus serving a dual purpose. About thirty licensing boards obtain from the American Medical Association verification of biographic data and other claims before granting a license or permission to take the licensing examination. This service is available to all licensing boards.

The tables referring to medical licensing board results include figures regarding the number of candidates for medical licensure in 1937, the number licensed and the number added to the profession.

LICENTIATES

The first table contains figures on the number of licenses issued in the various states, territories and possessions during the year. There were 9,793 licenses issued, 6,615 on the basis of examination and 3,178 by endorsement of credentials. In several states (table 12) the internship is a requisite for practice, but a physician is permitted to take the examination and if successful his license is withheld until completion of his internship. Licenses are also withheld for lack of citizenship or

minor technicalities. The figures therefore, for those licensed after examination include many who were examined in 1936 and even a few in previous years. New York issued the largest number of licenses, 1,655, California issued 616, Illinois 607 and Pennsylvania 597. A comparison with similar figures for 1935 and 1936 indicates marked increases in these states as well as many others. The states just named are the only ones

TABLE 1—Licentiates—1937

(CONTINUED FROM PAGE 1345)

National Board of Medical Examiners The total number licensed, 9,793, was 775 more than in 1936 and 1,883 more than in 1935 Licensed on the basis of examination, the figure increased 344 over 1936 and those licensed without examination increased 431 This figure, however, does not represent 9,793 individuals, since several have been licensed in more than one state during the year Nor does it represent additions to the medical profession at large, since the majority of the 3,178 licensed by endorsement, with the exception of those licensed in New York on the basis of foreign credentials, and many of the National Board diplomates have migrated from other states Table 7 shows how many of those licensed were never before registered and therefore represent the number added to the medical profession

TOTAL EXAMINED

Figures referring to those examined for medical licensure by individual states throughout the year, giving the number who passed and failed in each state, are included in table 2 There were 7,320 examined, of whom 6,589 passed and 731 failed, representing graduates from the sixty-seven approved four year medical schools in the United States and nine of the medical schools of Canada, eighty-seven faculties of medicine and five licensing corporations of other countries, ten medical schools now extinct, nine unapproved institutions and several osteopathic colleges Two undergraduates were examined Osteopaths granted the privilege to practice medicine, surgery or both by the medical board are included in these statistics eliminating, for instance, those osteopaths in California granted privileges as physicians and surgeons by the osteopathic board There were 5,707 graduates of approved medical schools in the United States examined, of whom 3.7 per cent failed, 129 graduates of approved Canadian

schools, 7.8 per cent of whom failed, 919 graduates of schools outside the United States and Canada, principally in Europe, with 30.8 per cent failures, 14 who graduated from schools now extinct with 21.4 per cent of failures, and 551 from unapproved and osteopathic schools and undergraduates, of whom 40.8 per cent failed These 551 represented 190 graduates of osteopathic schools, of whom 113 passed and 77, 40.5 per cent, failed, 359 graduates of unapproved schools, of whom 213 passed and 146, 40.7 per cent, failed and two undergraduates, both of whom failed The latter were permitted to take the examination in Mississippi by special acts of the legislature Graduates of osteopathic schools were examined in nine states—Colorado, Connecticut, Massachusetts, New Hampshire, New Jersey, Oregon, Texas, Wisconsin and Wyoming, while graduates of unapproved schools were examined in eleven states and Hawaii—Arizona, Arkansas, Florida, Illinois, Massachusetts, New Jersey, North Carolina, Ohio, Pennsylvania, South Dakota and Virginia Of the 190 osteopaths, 71 were examined in New Jersey, 62 in Massachusetts and 26 in Texas Of those graduates of other than recognized schools, Massachusetts examined 238, Illinois 85 and Ohio 23 Osteopaths in Colorado, Massachusetts, New Hampshire and New Jersey were examined in medicine and surgery and those in Connecticut, Oregon, Wisconsin and Wyoming in surgery only

The United States territories and possessions refer to Hawaii and Puerto Rico

The 7,320 examined do not represent individual since a candidate might take the examination in more than one state and would be counted in each state This applies to those who pass or fail, or those who fail and later pass in one or more states, or pass in one state

[illegible]

Hawaii Puerto Rico

and later within the same year fail elsewhere. However, if a physician fails more than once in a given state within the year he is counted in that state only once as a failure.

Three of the five homeopathic boards in existence, Connecticut, Delaware and Maryland, examined twenty-eight candidates all of whom passed. The homeopathic boards of Arkansas and Louisiana did not examine any one during the year. The one eclectic board in existence (Arkansas) examined and passed one candidate.

The largest number of graduates of any one school examined was 183 from Rush Medical College, who were examined in thirty states. There were 177 graduates of Jefferson Medical College of Philadelphia examined in nineteen states. The next highest number of graduates of any one school was the University of Illinois College of Medicine, which had 162 graduates examined by twenty states. Tufts College Medical School and Boston University School of Medicine had the highest percentage of failures in the United States, 18.2 and 14.5 respectively. Graduates of Rush Medical College were examined in the most states, thirty. Northwestern University Medical School graduates were examined by twenty-nine states, Harvard University Medical School by twenty-seven, the University of Pennsylvania School of Medicine by twenty-five. George Washington University School of Medicine by twenty-four. Georgetown University School of Medicine by twenty-one and the University of Illinois College of Medicine by twenty. All other schools had their graduates examined in fewer than twenty states. From those statistics it might be inferred that these schools educate more non-residents than do other schools. Graduates of the University of Southern California School of Medicine (forty-five) were examined by two

states, one of which was California which examined forty-four Graduates of Albany Medical College (nineteen) were also examined in two states, eighteen in New York where the school is located

Canadian graduates took the test in twenty-three states and Puerto Rico. The greatest number, fifty-one represented McGill University Faculty of Medicine who were examined in sixteen states, twenty-four graduates of the University of Toronto Faculty of Medicine were examined also in sixteen states, while fourteen graduates of Dalhousie University Faculty of Medicine and six of the graduates of the University of Alberta Faculty of Medicine were examined in six states. The highest percentage of failures was 25 representing the University of Montreal Faculty of Medicine.

Sixteen medical schools had no failures before state licensing boards, namely the Universities of California, Southern California, Colorado, School of Medicine of the Division of the Biological Sciences, Indiana, Iowa, Kansas, Louisiana, Minnesota, Duke, Western Reserve, Oklahoma, Oregon, Baylor, Texas and Vermont.

In 1936, 6,908 were examined of whom 6,214 passed and 100 per cent failed, as compared with 7,320 examined in 1937, of whom 6,559 passed and 731 100 per cent failed. There were 412 more examined than in 1936 375 more passed and the failures increased thirty-seven. Elsewhere are given figures representing actual licentiates and additions to the medical profession.

FAILURES

In table 3 are presented for each state the number granted licenses to practice medicine having a perfect record in medical license examinations the number

(CONTINUED ON PAGE 11)

TABLE 4—Credentials Presented by Physicians for Licensure by Reciprocity and Endorsement—1937

[illegible]

(CONTINUED FROM PAGE 1349)

licensed after one failure and after two or more failures, these two groups being classified by indication whether the failure or failures have been in the state in which they are receiving a license or elsewhere

Of the total number licensed by examination, 6,615, 190 failed after one examination in the state in which they were licensed in 1937 and 63 elsewhere, while 99 failed more than once in the state awarding the 1937 license and forty elsewhere, leaving 6,223 licensed without ever having failed a medical licensing examination

In the computation of this table it was noted that five osteopaths were licensed in Massachusetts, of whom one failed fourteen and another ten times. Of the thirty-nine graduates of unapproved schools licensed in Massachusetts two failed thirteen, four failed ten, three nine, two eight and two seven times each. An osteopath was examined four times in Connecticut, another in New Hampshire failed four times. Texas licensed an osteopath who failed the Delaware osteopathic examination. North Carolina also licensed a graduate of an unapproved school who had five failures.

Nineteen states and the District of Columbia licensed physicians who never failed a state board examination while Massachusetts licensed 77 and New York 189 who previously failed. Licensure of candidates with failures occurred in twenty-nine states, but with the exception of Massachusetts and New York no state licensed more than ten.

REGISTRATION BY RECIPROCITY AND ENDORSEMENT

Table 4 records the number of physicians granted licenses to practice medicine and surgery without examination on presentation of satisfactory credentials. These individuals presented licenses from other states, Canada and foreign countries, the certificate of the National Board of Medical Examiners, one of the government services, or other credentials.

Definite reciprocal agreements exist in many of the states, but some will register licentiates who present credentials which correspond to those required by their respective states at the time such licenses were issued. The medical practice acts of many give the examining board the privilege of using its discretion in determining the acceptability of a candidate. The reciprocity and endorsement policies of the various states are presented in table 6. In addition there is also indicated whether licenses are granted to diplomates of the National Board of Medical Examiners or to retired officers of the government services. Specific requirements such as professional practice, basic science certificate and oral examination is recorded as is also the fee demanded. Florida, Massachusetts and Rhode Island do not have reciprocal or endorsement arrangements with any state. Reciprocal relations were canceled in Idaho in 1937. Massachusetts and Rhode Island, however, will register diplomates of the National Board of Medical Examiners by endorsement. Those desiring licenses in Arizona, Arkansas, Colorado, Connecticut, District of Columbia, Iowa, Michigan, Minnesota, Nebraska, Oklahoma, Oregon, Washington and Wisconsin are required to obtain a certificate from the board of examiners in the basic sciences before being eligible for licensure. Other requirements or exemptions are mentioned in footnotes.

Referring to table 4, it will be noted that New York granted the greatest number of licenses by endorsement in 1937 (586), California was second with 268, Michigan third with 188, Texas fourth with 171. New Jersey

and Ohio each licensed 140, and 119 were registered in Illinois. All other states licensed fewer than 100. The largest group representing the same type of credentials were the 559 diplomates of the National Board of Medical Examiners. More than 100 physicians from Illinois, Maryland, Missouri, New York, Ohio and Tennessee, respectively, were licensed in the various states and 153 candidates from Canada and foreign countries were likewise registered, 146 of the latter being so endorsed in New York. Only 171 New York licenses were endorsed during the year, while 586 candidates were licensed in New York on the basis of credentials.

TABLE 3—Failures Before Medical Licensing Boards by Licentiates of 1937

* Hawaii, Puerto Rico

Six physicians were licensed, one each in Arizona, New Hampshire and New York by endorsement of the credentials of the Medical Council of Canada, one physician was endorsed in New Mexico and one in New York on a license issued in Ontario and one in Vermont on Quebec credentials. Licenses were issued by endorsement of European credentials in two states, New Hampshire and New York. Three were so registered in New Hampshire on the basis of certificates from Germany. Those in New York (144) represented the following countries: Austria four, Czechoslovakia one, Dominican Republic one, France one, Germany 127, Hungary six,

13 Applicant must have resided in the state used as basis of application for one year after date on said certificate or in lieu of residence must show proof of two years legal practice in some state or territory of the United States (Internship accepted as residence)

14 Oral examination required

15 Unless in practice in another state for five years

16 Six months of which must be just preceding application

17 Practical clinical examination required

18 Same as charged Kansas

19 Regular and Homoeopathic boards

20 Canada excepted

21 Regular board

22 Fee same as applicant's state charges if more than \$50

23 Oral examination required if applicant's state requires it

24 If an applicant passes the examination in the state from which he transfers after the completion of his internship no practice is required

25 Internship accepted if served in this state

26 Internship accepted—considered equivalent to two years practice

27 Five years practice

28 Conditionally

29 A two year internship is accepted

30 License by National Board certificate at examination fee of \$15 unless holding a license from another state

In table 5 the 3,098 physicians licensed by reciprocity and endorsement and, in addition, eighty osteopaths so licensed, are recorded by school of graduation and state or territory where licensed. All of the existing medical schools in the United States and eight in Canada offering the complete medical course were represented. The largest number of graduates of any one school were from Northwestern University Medical School 101. Harvard had 93 licensed by this method, St. Louis University School of Medicine 88. Rush

and several osteopathic schools were licensed without examination.

Seventy-two osteopaths in Texas and two in New Hampshire were granted the right to practice medicine and surgery, and two and four osteopaths, respectively, permitted the privilege of practicing surgery in Wisconsin and Wyoming. There were 238 graduates of foreign medical faculties registered, 76 from extinct medical schools and 104 graduates of unapproved schools, a total of 418. Of the remainder

(2,760), 2,712 were from approved medical schools in the United States and forty-eight from the Canadian schools

CANDIDATES ADDED TO THE PROFESSION

Licentiatees representing additions to the profession during 1937 are given in table 7. The figures represent candidates examined in 1937 and licensed, also those examined in previous years whose licenses were withheld and issued in 1937, those certified on the basis of the certificate of the National Board of Medical Examiners, government services, Canadian and foreign

* Hawaii, Puerto Rico

credentials and miscellaneous. In the main they represent recent graduates. Altogether, 6,403 were added to the profession as contrasted with approximately 4,000, the number removed by death in 1937. These figures indicate that at least 1,500 have been added to the medical profession. It is assumed that the great majority of those licensed are in practice. It is interesting to note that, of 9,793 licenses issued throughout the year, 6,403, 65.4 per cent, are actual additions to the medical profession. The largest number added to the profession was in New York, 1,287, Pennsylvania added 476 and Illinois 464, while Montana and Wyoming added two. More than 300 were added in California and Ohio. Between 200 and 300 were added to the physician population of Maryland, Massachusetts, Michigan, New Jersey, Tennessee and Texas. Indiana,

Louisiana, Minnesota, Missouri, Virginia and Wisconsin increased their population of physicians between 100 and 200. Thirty-one states, the District of Columbia, Hawaii and Puerto Rico added less than 100. Of the number of licentiatees represent

ing additions to the medical profession during 1937, 5,802 secured this privilege by examination and 601 by the endorsement of credentials. A great majority of the latter were licensed in New York and represent graduates of foreign medical schools.

licensed on the basis of their foreign credentials and diplomates of the National Board of Medical Examiners. In 1935 there were 5,098 added by means of examination and 411 by endorsement of credentials, a total of 5,509. In 1936 there were 665 more added than in 1935 and, in 1937, 229 more than in 1936 and 894 more than in 1935. No additions were made to the physician population of Alaska, but twenty-six were added in Hawaii and Puerto Rico.

each, the Pacific group of states 403, the East South Central 320 and the Mountain division 108. Fourteen were added in Puerto Rico and twelve in Hawaii.

In table 9 those representing additions to the medical profession are arranged by schools, the same as those examined are listed in table 2—existing approved medical schools in the United States and Canada, foreign faculties of medicine, schools now extinct and unapproved schools.

Table 8 records the licentiates representing additions to the medical profession by nine geographic divisions in 1937, namely, the New England, Middle Atlantic, East and West North Central, South Atlantic, East and West South Central, Mountain and Pacific states as well as the Territory of Hawaii and Puerto Rico. The largest number was added to the Middle Atlantic group, 2,014; the East North Central 1,291, the South Atlantic 658; the West North Central 605; the New England and West South Central group 489.

The 6,403 physicians representing additions to the medical profession included graduates from the sixty-seven approved medical schools of the United States, nine schools in Canada, and others. The greatest number from any one school were 145 from Rush Medical College; 143 from the University of Minnesota Medical School; 142 were from Northwestern University Medical School and 141 from the University of Michigan Medical School and Jefferson Medical College of Philadelphia. Of the United States schools the Albany

CHART 1—STATES REGISTERING OTHER THAN GRADUATES OF APPROVED MEDICAL SCHOOLS—1937

Map copyright by Rand McNally & Company Chicago

The states in black registered more than 5 such candidates those shaded 5 or less

Medical College had the fewest, twenty-four, while only three were represented from the Universities of Manitoba and Montreal. There were 729 graduates of foreign faculties of medicine and 381 from unapproved schools.

STATE REQUIREMENTS OF PRELIMINARY EDUCATION

The minimum requirement of preliminary education exacted by the Council on Medical Education and Hospitals since 1918 has been two years of college work. Five states, however, have not revised or

Requires a two year internship

United States and four in Canada exact the internship requisite. A few of the medical schools will accept research or other clinical work in lieu of the internship.

As revealed in table 12, twenty states, Alaska and the District of Columbia require that applicants for licensure possess a hospital internship. The first exacting this requirement was Pennsylvania in 1914. The

requirement in New Hampshire became effective in 1938, while in Alabama and Louisiana it will be a requirement beginning with 1939.

REGISTRATION 1904-1937

A study of totals and percentages (table 13) for thirty-four years (1904-1937) is of interest. The

| 1933 | 5 939 | 7.6 | 1 987 | 7 226 |
| 1934 | 5 622 | 8.4 | 2 157 | 7 779 |
| 1935 | 5 847 | 9.1 | 2 194 | 8 041 |
| 1936 | 6 214 | 10.0 | 2 747 | 8 961 |
| 1937 | 6 589 | 10.0 | 3 178 | 9 767 |

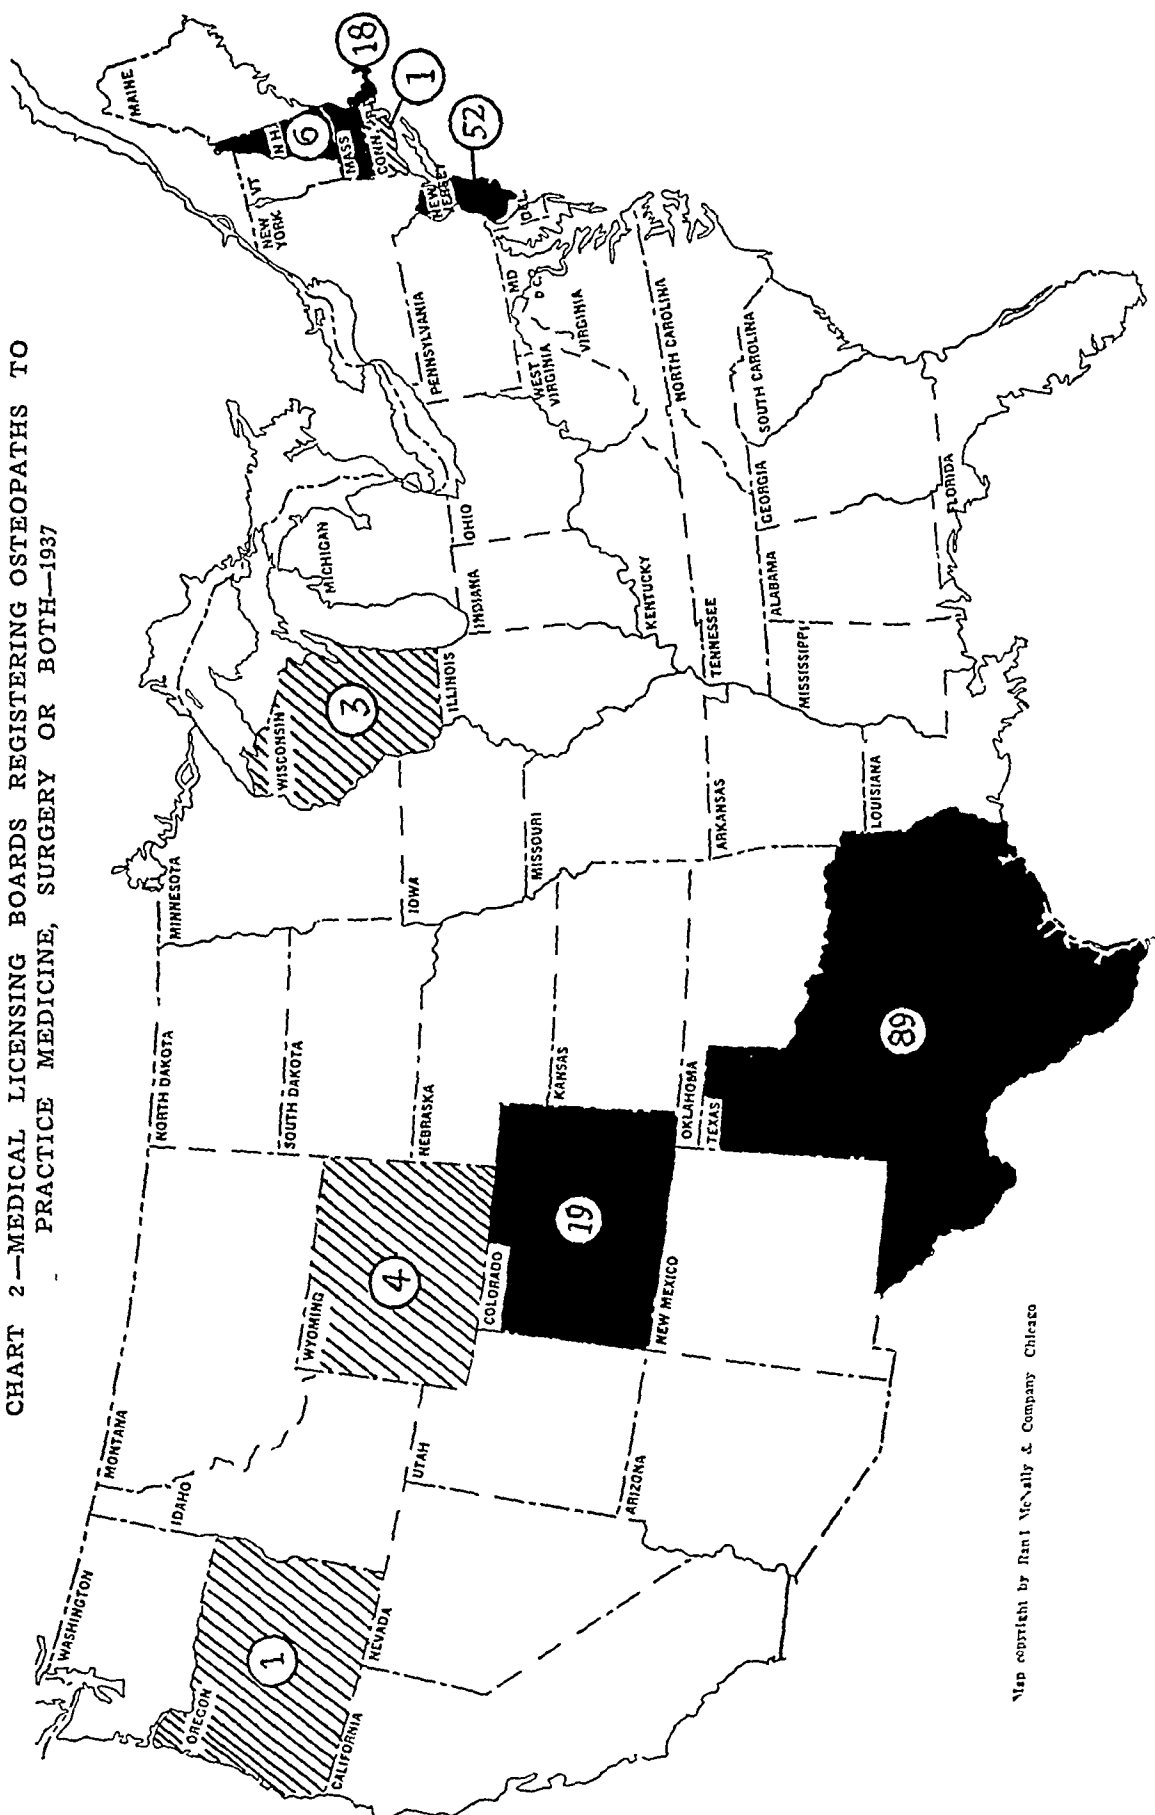

number (6,589) who passed in 1937 was 375 more than in 1936 and 899 more than in 1904. The number registered without examination, 3,178, was 431 more than in 1936. Contrasting these figures with those for 1904 will show the great use being made of this system of licensure. By both methods, examination and endorsement of credentials, 9,767 were registered, 806 more than in 1936. This figure represents the largest number of candidates registered in thirty-four years.

Ten per cent of those examined failed in 1937 as compared with 19.3 per cent in 1904. The failures in recent years represent to a large extent graduates of unapproved schools and foreign faculties.

While these figures represent those registered in the years given, they do not in all states represent the number licensed in a given year. Licenses are withheld in many states, as indicated in the text describing table 1.

There appears to be no marked increase or decrease in the total number of candidates registered from 1904 to 1933, but in the last five years the number registered has been markedly increasing. However, the number

CHART 2—MEDICAL LICENSING BOARDS REGISTERING OSTEOPATHS TO
PRACTICE MEDICINE, SURGERY OR BOTH—1937

The states in black registered more than 5 such candidates those shaded 5 or less

licensed without examination since 1906 has been rapidly increasing, owing to the almost universal system of endorsement and the recognition of the certificate of the National Board of Medical Examiners. The decrease in the number registered in 1918 was due to the sudden withdrawal of physicians and recent graduates from civilian life. Again in 1922 there was a notable reduction, this figure representing the small class that began the study of medicine in 1918. There has been a substantial increase in the number registered in 1936 and a still larger increase in 1937 both by examination and by endorsement. The graduating classes of the approved medical schools for these two years were 5,183 and 5,377 respectively. It may be anticipated that within the next few years the number of those registered to practice medicine and surgery will decrease, as there has been a reduction in medical school enrolment. In seventy-seven schools there were 22,888 students enrolled in 1935, 22,564 in 1936 and 22,095 in 1937. Classes in subsequent years in many cases will be reduced.

SOURCE OF PHYSICIANS REGISTERED

The educational fitness of the individuals registered in the last sixteen years, 1922-1937, is shown in table 14. Of the 9,767 registered by all methods in 1937, 8,363, or 85.6 per cent, graduated from approved medical schools and there were 1,404, 14.4 per cent, other practitioners registered. In the computation of these figures, all schools rated as class A and B by the Council on Medical Education and Hospitals since 1907 are classified as approved. In the column "Others" are included graduates of institutions prior to 1907, of foreign faculties of medicine, class C graduates, undergraduates, osteopaths, and graduates of schools that have been refused all recognition as medical schools.

Of the 9,767 graduates registered in 1937, 6,589 were registered after examination and 3,178 by endorsement. There were 5,617 graduates of approved medical schools examined and 972 others. Likewise among those reg-

istered by endorsement there were 2,746 approved graduates and 432 others. Approved graduates, those physicians who graduated prior to the first classification of medical schools and graduates of foreign faculties of medicine were registered in Alabama, Delaware, Idaho, Indiana, Iowa, Kansas, Louisiana, Maine, Maryland, Michigan, Minnesota, Mississippi, Montana, Nevada, North Dakota, Oklahoma, Rhode Island, South Carolina, South Dakota, Tennessee, Utah, Vermont, Washington, West Virginia, Alaska and Puerto Rico.

GRADUATES OF OTHER THAN APPROVED MEDICAL SCHOOLS AND OSTEOPATHS REGISTERED

In table 15 will be noted the total number of graduates of those institutions which have been classified as unapproved who were registered with or without examination from 1934 to 1937 inclusive.

Thirteen states and Hawaii registered 233 graduates of unapproved medical schools in 1937, 211 by examination and twenty-two without examination. The

number of unapproved graduates increased by thirteen the number registered in 1936. One each was licensed in Nebraska, Pennsylvania, Virginia and Hawaii. No undergraduates were licensed in 1937, although two were examined. The twenty-three licensed by examination in Ohio and fourteen by endorsement in New York, three in New Jersey, two in Florida and Kentucky and one in Pennsylvania are graduates of the Eclectic Medical College of Cincinnati, which does not enjoy the approval of the Council on Medical Education and Hospitals but is approved by the states named. This school has not enrolled any new students for several years and plans to graduate its last class in 1939, when it will close. The 253 licensed in four years in Massachusetts represent mainly two unapproved schools located in that state and a few elsewhere. This state by law is required to admit to its examination a graduate of any chartered medical school but in 1936 amended its medical practice act appointing an approving authority. This new law goes into effect in 1940. The 266 graduates of the Chicago Medical School, an unapproved school, were registered by examination in Illinois in four years.

In the four year period shown, 622 graduates of unapproved schools and undergraduates were registered by examination and fifty-seven by reciprocity, a total of 679.

Chart 1 indicates by shaded lines those registering fewer than six graduates of unapproved medical schools and by a solid area those registering more than five such candidates during 1937.

In table 16 are given the number of graduates of schools of osteopathy who were registered with or without examination in 1934 to 1937 inclusive.

CHART 3—STATES REGISTERING GRADUATES OF MEDICAL FACULTIES ABROAD—1937

Map copyright by Rand McNally & Company Chicago

The states in black registered more than 5 such candidates those shaded 5 or less

In 1937, nine states registered 113 by examination and eighty by endorsement of credentials. These osteopaths were registered in Colorado, Connecticut, Massachusetts, New Hampshire, New Jersey, Oregon, Texas, Wisconsin and Wyoming.

These osteopaths were granted the right to practice medicine, surgery or both by the Board of Medical Examiners. These facts for 1937 are shown graphically in chart 2.

Seventy-seven osteopaths failed of registration by examination as follows: two in Colorado and Connecticut, forty-four in Massachusetts, nineteen in New Jersey, nine in Texas and one in Wyoming.

In the four year period 1934-1937, 383 graduates of osteopathic schools secured the privilege of practicing medicine, surgery or both in nine states.

In Colorado osteopaths are admitted to the examination for a license to practice medicine. They have no separate board. The statute of Colorado is silent with respect to the scope of practice authorized by a license issued to osteopaths.

The Connecticut statute provides that any registered osteopath may practice either medicine, surgery or both, as the case may be, after passing a satisfactory examination before the medical examining board.

The Massachusetts statute, by definition, includes osteopathy in the practice of medicine and does not differentiate the type of license issued to an osteopathic applicant. The medical practice act requires that any applicant for license to practice must be in possession of a degree of doctor of medicine, or its equivalent, from a legally chartered medical school that gives a full four year course of instruction of not less than thirty-two weeks in each year. As has been said, the Massachusetts statute has been amended.

In New Hampshire osteopaths are granted the right to practice medicine and surgery by the Board of Registration in Medicine.

Osteopaths who are duly registered and licensed to practice osteopathy in the state of New Jersey, who present three years of practice of surgery in a hospital

approved by the Board of Medical Examiners, may be admitted to the examination to be licensed to practice medicine and surgery.

Osteopaths are granted the privileges of surgery in Oregon by the Board of Medical Examiners.

The statutes of Texas provide for the issuing of a license to practice medicine only. So far as the statutes indicate, the osteopaths are not restricted in their field of practice.

In Wisconsin and Wyoming osteopaths are granted the right to practice surgery.

It is to be regretted that such persons as those described in tables 15 and 16 are granted the right

to practice medicine or surgery. The medical profession should be ever watchful and untiring in its efforts to prevent osteopaths and others from gaining the legal right to practice medicine or surgery, for which their training is wholly inadequate. If the licensing boards were more fully conscious of their responsibility to protect the citizens of their respective communities from ignorance and incompetence masquerading as medical skill, we should not continue to have year after year licenses granted to persons whose training falls so far short of the currently accepted standards of medical education.

TABLE 17—*Annual Registration*

| Kansas | Utah |
| Louisiana | Wyoming |
| Minnesota | |

Five states—Alabama, Delaware, Florida, Mississippi and North Carolina—require physicians to pay annually an occupational or commercial tax. The fee for this registration is generally \$2.

ANNUAL REGISTRATION

Eighteen states, as shown in table 17, require that all physicians licensed register annually, whether or not they reside in the state.

GRADUATES OF FACULTIES OF MEDICINE ABROAD

A study of the number of students from the United States pursuing medical courses in Europe has been carried on by the Council on Medical Education and Hospitals since 1931. There were in 1937 more than 1,500 studying abroad who in all probability plan to return to the United States to practice. Table 18 presents statistics on the number of graduates of faculties of medicine abroad examined for licensure in 1937. It is not known how many of these are foreign born but many of those licensed each year represent students from the United States. The figures in the accompanying tabulations therefore represent both American and foreign born physicians. Eighty-seven medical schools, excluding five licensing corporations, of eighteen European and seven other countries were represented. There were 919 examined, of whom 636 passed and 283, 30.7 per cent, failed. Graduates of the University of Berlin were licensed in fourteen states and the University of Munich and Budapest in ten states. All other schools were represented in less than eight states. Twenty-six states, Hawaii and Puerto Rico examined physicians educated abroad. The state of New York had the greatest number, 596, of whom 397 passed and 199, 33.3 per cent, failed. New Jersey examined fifty-nine with thirteen, 22 per cent, of failures. Maryland was third with fifty-two examined, twenty-eight passed and twenty-four, 46.1 per cent, failures.

In addition to the figures represented in this table, 238 graduates of foreign medical faculties were licensed in 1937 without examination and 147 of the 238 so registered were granted licenses on the basis of their foreign diplomas and licenses, while the remainder, 91, had already been examined by a medical board in this country.

Chart 3 shows in graphic form the states which during 1937 registered graduates of foreign medical

(CONTINUED FROM PAGE 1363)

faculties by examination, endorsement or both. From a perusal of tables 2, 4 and 5 it can be ascertained how many were licensed by both these means in the various states. The states which licensed more than five graduates are indicated in black on the chart, those shaded, five or less.

In table 19 are assembled figures showing the standing during the six year period 1932-1936 of the graduates of faculties of medicine outside the United States and Canada admitted to licensing examinations in this country. A similar tabulation is presented for the year 1937. One hundred and twenty-eight schools and nine licensing corporations of Great Britain were represented. During the five year period 1,688 were examined and in 1937, 919. The largest number represented the

and were introduced in several states. In table 1 is shown the years in which the various acts were enacted.

Statistics based on the number of candidates certified in 1937, and those who failed to secure this certification, together with the totals for other years shown for comparison, are included in the accompanying tabulations.

TABLE 2—Subjects of Examinations

| | Examinations Required in | | | | | | |

| Michigan | + | + | + | | + | + | + |
| Minnesota | + | + | + | | + | + | + |
| Nebraska | + | + | + | | + | + | + |
| Oklahoma | + | + | + | | + | + | + |
| Oregon | + | | + | | + | + | + |
| Washington | + | | + | | + | + | + |
| Wisconsin | + | | | + | | + | + |

The subjects in which examinations are conducted in the respective states and the District of Columbia are given in table 2. The subjects included in basic science examinations are specified by the statutes. The examining boards may neither add to nor subtract from such subjects.

Applicants examined during 1937 in the various groups—physicians or medical students, osteopaths, chiropractors and those unclassified—are included in table 3. There were 1,344 examined by twelve boards. Of this number 1,231 were doctors of medicine or medical students (referred to hereafter for clarity as

BASIC SCIENCE BOARDS

A certificate in the basic sciences is a prerequisite to licensure in twelve states and the District of Columbia. While the laws of some of these states include reciprocal agreements, the certificate is obtainable after examina-

TABLE 1—States Having Basic Science Laws and Year of Enactment

| State | Year Enacted | State | Year Enacted |
|----------------------|--------------|------------|--------------|
| Arizona | 1903 | Minnesota | 1927 |
| Arkansas | 1929 | Nebraska | 1927 |
| Colorado | 1937 | Oklahoma | 1937 |
| Connecticut | 1925 | Oregon | 1933 |
| District of Columbia | 1909 | Washington | 1927 |
| Iowa | 1900 | Wisconsin | 1925 |
| Michigan | 1937 | | |

tion in the majority of instances. Boards for certification of candidates functioned during 1937 in ten states and the District of Columbia and a board has functioned since July 1937 in Colorado, while in Michigan an examining board has not yet been appointed. The ten states include Arizona, Arkansas, Connecticut, Iowa, Minnesota, Nebraska, Oklahoma, Oregon, Washington and Wisconsin. In 1937 basic science requirements were established in Colorado, Michigan and Oklahoma

physicians), sixty-four osteopaths and eighteen chiropractors, and for thirty-one it was not possible to determine what profession they represented. In applying for a basic science certificate it is not necessary in several of the states to mention the school of practice, but by checking the biographic records of the American Medical Association it has been possible to determine what profession the majority of the candidates represented. The remainder composed the unclassified group. Of all examined, 1,102 passed and 242 failed, 18.0 per cent. Of the physicians examined 13.8 per cent failed, of the osteopaths 53.1 per cent, of the chiropractors 72.2 per cent and of those unclassified 80.6 per cent. There were 1,061 physicians who passed,

thirty osteopaths, five chiropractors and six unclassified Minnesota examined the largest number, 235, of whom 21.3 per cent failed. The next largest number, 180, were examined in Wisconsin, with 8.3 per cent failures. Osteopaths were examined in Arizona, Arkansas, Connecticut, Iowa, Minnesota, Oklahoma, Oregon, Washington and Wisconsin. Chiropractors were examined in Connecticut, Minnesota, Washington and Wisconsin. One state, Arkansas, examined forty-five physicians and three osteopaths, all of whom passed. In the two states which examined for the first time during 1937, namely, Colorado and Oklahoma, there were examined, respectively, thirteen physicians in Colorado and 111 physicians and nine osteopaths in Oklahoma. Of those examined in Colorado 23.1 per cent failed, and in Oklahoma 15.8 per cent. The highest percentage of failures (41.1) was in Iowa, which examined eighty-six physicians, sixteen osteopaths and ten unclassified candidates.

The number of certificates granted by examination, reciprocity and endorsement are listed in table 4. A total of 1,102 certificates were granted after examination, of which 1,061 were issued to physicians, thirty to osteopaths, five to chiropractors and six to persons who were unclassified. There were 175 candidates certified without examination, by reciprocity or endorsement, consisting of 165 physicians and ten osteopaths. Minnesota accepted the greatest number without examination, sixty, of whom fifty-nine were physicians and one an osteopath. Wisconsin registered forty-five physicians and three osteopaths by this method, and Arkansas twenty-three physicians and two osteopaths. Arizona, Connecticut, the District of Columbia, Oklahoma and Washington licensed none without examination. Arizona and Washington, by law, have no reciprocal agreements. No chiropractors or those in the unclassified group were licensed without examination.

Table 5 shows the number of candidates examined and certified from 1927 to 1937 inclusive. In 1928, when five boards were functioning, there were 646 physicians examined, of whom sixty, or 9.3 per cent,

physicians were certified without examination, while only sixty-five other practitioners were so registered.

Altogether, 8,792 certificates have been issued by basic science boards since 1927, of whom 8,372 were granted to physicians and 420 to other practitioners. From the high percentage of failures in the other practitioner group it seems apparent that the enforcement

| Totals | | 8,202 | 7,222 | 980 | 11.9 | 1,150 | 774 | 333 | 440 | 56.9 | 49 |

of basic science laws affects most seriously this group. Examination of the records of a considerable number of states having basic science laws will show that before such laws were enacted the number of other practitioners appearing for examination and licensure was very considerable and was growing. The object of these boards has been to provide a means of insuring that all candidates seeking authority to care for sick and injured people shall first possess a reasonable knowledge of the sciences fundamental to the healing art.

NATIONAL BOARD OF MEDICAL EXAMINERS

The National Board of Medical Examiners organized in 1915, conducts examinations and awards successful candidates a certificate which is regarded as an adequate qualification for the practice of medicine. Since 1922 its examination has been given in three parts, parts I and II being written examinations and part III a practical and clinical examination. Data are presented regarding the examinations and the issuance of certificates and include tables enumerating the results of examinations in parts I, II and III for each calendar year, excluding duplication by counting the last examination if more than one part is taken within the year, and also of those certified or failing of certification. Also figures from compilations not reproduced here are discussed. Similar data have been presented in the State Board Number of THE JOURNAL for twenty years.

Four examinations were held in parts I and II during 1937, at which 1,435 and 855, respectively, were examined. In part I, 871 passed and 149, 14.6 per cent failed, while, in part II, 803 passed and 60 per cent failed. In part I 415 took incomplete examination. Candidates are required to take all six subjects of part I at a regular examination period unless entitled to take an incomplete examination or electing to take a divided examination. An incomplete examination is arranged for candidates taking part I at the end of their second medical year in schools whose third year curriculum include courses in one or two subjects of this part. II

| Totals | 1,061 | 30 | 5 | 6 | 1,102 | 165 | 10 | 0 | 0 | 175 | 1,277 |

failed and fifty-nine other practitioners, of whom twenty-eight, or 47.5 per cent, failed. In 1937, 1,226 physicians and fifty-one other practitioners were certified. During the eleven year period a total of 8,202 physicians were examined, of whom 980, 11.9 per cent, failed and 774 other practitioners, of whom 419, 54.1 per cent failed. During this period, 1,150 physi-

subjects thus postponed may be taken at any examination period after the candidate has completed them in his medical school. Any candidate not entitled to take an incomplete examination in part I may, if he so elects, take a divided examination by writing any four subjects at one time and the remaining two within thirteen months, but after at least one semester of study. Incomplete examinations were not included when percentages were being computed, since they represent neither a candidate eligible for certification nor a failure. One candidate took an incomplete examination in part II.

Since 1922 a total of 15,722 examinations have been given in part I and 8,257 in part II. From 1922 to 1937 inclusive 10,031 individuals were successful in passing part I and 7,434 in passing part II. The figures for those examined include 4,071 incomplete examinations in part I and thirty-six in part II. The figures cover the totals of each examination given during a calendar year and include some who fail and are reexamined during the same year and also some who pass parts I and II in the same year. Therefore they represent examinations conducted rather than individuals examined. In the sixteen year period since 1922 there have been 1,620 failures in part I, 13.9 per cent, and 787 in part II, 9.6 per cent.

TABLE 1—Examinations in Part III

| Examinations of | Total Examined* | Passed | Failed | Percentage Failed |
|-----------------|-----------------|--------|--------|-------------------|
| 1922 | 22 | 22 | 0 | 0.0 |
| 1923 | 82 | 61 | 1 | 1.2 |
| 1924 | 126 | 120 | 6 | 4.8 |
| 1925 | 219 | 206 | 13 | 5.9 |
| 1926 | 255 | 243 | 12 | 4.7 |
| 1927 | 293 | 242 | 21 | 7.2 |
| 1928 | 372 | 306 | 16 | 5.0 |
| 1929 | 351 | 337 | 15 | 4.3 |
| 1930 | 420 | 401 | 19 | 4.5 |
| 1931 | 457 | 419 | 18 | 4.1 |
| 1932 | 500 | 522 | 23 | 5.1 |
| 1933 | 551 | 526 | 25 | 4.5 |
| 1934 | 567† | 548 | 19 | 3.4 |
| 1935 | 595‡ | 578 | 20 | 3.3 |
| 1936 | 566§ | 547 | 29 | 5.0 |
| 1937 | 668§ | 630 | 38 | 5.7 |
| Totals | 6,044 | 5,758 | 280 | 4.6 |

* Between 1916 and 1921 a total of 325 were examined of whom 268 passed and 57.14 per cent failed. Total certificates awarded 6,076. During this period only one examination for the certificate was given.

† Excluding referred examinations.

‡ Excluding 41 referred.

§ Excluding 53 referred.

In 1922, 388 were examined in part I with 20.3 per cent failures, as compared with 1,435 in 1937 with 14.6 per cent failures. In part II in 1922, 109 were examined and 17.4 per cent failed while, in 1937, 855 were examined and 5.1 per cent failed.

The results of examinations in part III for the sixteen year period 1922 to 1937 inclusive are represented in table 1 reproduced here. In 1937 668 were examined as compared with only twenty-two in 1922. Of the number examined in 1937 thirty-eight or 5.7 per cent failed. The highest percentage of failures was in 1927, when 293 were examined and twenty-one 7.2 per cent failed. During 1937 630 were granted certificates. In sixteen years 6,044 were examined of whom 5,758 were granted certificates and 280 4.6 per cent, failed. Here again a candidate having failed may subsequently receive a certificate.

From 1916 to 1921 when the examination was not given in three parts 325 were examined of whom 268 passed and 57.14 per cent failed. Altogether from 1916 up to and including 1937 6,026 certificates have been granted.

The number of persons examined during any one year is given in table 2. The classification as passed or failed, in cases in which more than one examination has been taken in a given year, was based on the results of the last examination during the year in question. For example, if in 1937 a candidate passed part I but later failed part II, he is listed as having failed. Taking this

TABLE 2—Parts I, II and III, Excluding Duplications

| | Total Examined | Passed | Incomplete | Failed | Percentage Failed |
|--------|----------------|--------|------------|--------|-------------------|
| 1922 | 570 | 381 | 58 | 86 | 18.4 |
| 1923 | 770 | 594 | 79 | 102 | 14.7 |
| 1924 | 918 | 756 | 69 | 153 | 16.8 |
| 1925 | 1,167 | 915 | 50 | 202 | 18.1 |
| 1926 | 1,161 | 930 | 105 | 126 | 11.9 |
| 1927 | 1,248 | 947 | 142 | 159 | 14.4 |
| 1928 | 1,430 | 1,101 | 211 | 118 | 9.7 |
| 1929 | 1,723 | 1,290 | 319 | 124 | 8.8 |
| 1930 | 2,044 | 1,547 | 322 | 175 | 10.2 |
| 1931 | 2,218 | 1,632 | 410 | 176 | 9.7 |
| 1932 | 2,342 | 1,850 | 350 | 137 | 6.9 |
| 1933 | 2,277 | 1,806 | 250 | 191 | 9.6 |
| 1934 | 2,261 | 1,801 | 330 | 130 | 6.7 |
| 1935 | 2,368 | 1,831 | 405 | 129 | 6.6 |
| 1936 | 2,515 | 1,987 | 353 | 175 | 8.1 |
| 1937 | 2,735 | 2,151 | 397 | 187 | 8.0 |
| Totals | 27,767 | 21,509 | 3,888 | 2,370 | 9.9 |

into consideration, there were 2,735 who took at least one of the examinations of the National Board of Medical Examiners during 1937, as compared with 525 in 1922. A total of 27,767 were examined in one or more of the examinations in the sixteen years shown, of whom 21,509 passed, 2,370 failed, 3,888 took incomplete examinations and 9.9 per cent failed.

Diplomates licensed on the basis of their credentials have increased from only two in 1917 to 559 in 1937, 4,120 having been so licensed since the National Board was created. A total of 6,026, however, have received the certificate of the National Board. In 1937, 559 diplomates were registered on the basis of credentials in forty states, the District of Columbia, Alaska, Hawaii and Puerto Rico.

The certificate of the National Board of Medical Examiners is granted recognition by the licensing boards of forty-two states and Alaska, Canal Zone, Hawaii and Puerto Rico (table 3).

Some of these boards have additional requirements. Diplomates of the National Board of Medical Examiners are admitted to the final examination given by the Conjoint Examining Boards of England and Ireland.

TABLE 3—States Endorsing Certificates of National Board of Medical Examiners

| | | | |
|-------------|---------------|----------------|----------------|
| Alabama | Indiana | Nevada | Rhode Island |
| Alaska | Iowa | New Hampshire | South Carolina |
| Arizona | Kansas | New Jersey | South Dakota |
| Arkansas | Kentucky | New Mexico | Tennessee |
| California | Maine | New York | Utah |
| Canal Zone | Maryland | North Carolina | Vermont |
| Colorado | Massachusetts | North Dakota | Virginia |
| Connecticut | Minnesota | Ohio | Washington |
| Delaware | Mississippi | Oklahoma | West Virginia |
| Georgia | Missouri | Oregon | Wyoming |
| Hawaii | Montana | Pennsylvania | |
| Illinois | Nebraska | Puerto Rico | |

and the Triple Qualification Board of Scotland. The certificate is recognized also in South Africa, Spain, Syria and Turkey.

Examinations in parts I and II are held at class A medical schools where there are five or more candidates available, and part III is held in twenty-two established centers throughout the United States.

SATURDAY, APRIL 23, 1938

MEDICAL EDUCATION AND LICENSURE

Ten years before the Declaration of Independence, the colony of New York enacted a statute, the first of its kind in the New World, fixing professional qualifications for the practice of medicine. It forbade such practice to all who failed to satisfy the legal requirements, namely, a satisfactory examination conducted by the governor of the province, a judge and an officer of his majesty's army. In all our states similar legislation has been adopted. From time to time variations in the precise method of determining the candidate's fitness have been introduced. Once membership in a medical society was proposed as a necessity, another time a diploma from a medical school was required. During the last quarter of the nineteenth century most of the states set up official boards to test by examination the fitness of candidates for medical licensure.

After several years' study the first classification of medical schools by the Council on Medical Education of the American Medical Association, published in 1907, showed that there were many low grade proprietary schools the graduates of which should not even be permitted to take the licensing examination. This conclusion the Carnegie Report of 1910 abundantly confirmed. Although many states have taken steps to exclude the graduates of low grade schools, it is disconcerting to find that after thirty years there are still thirteen states¹ in which graduates of unrecognized institutions are being admitted to practice.

In Arizona the law requires that candidates for medical licensure shall be graduates of schools which maintain standards "not less than those prescribed by the Association of American Medical Colleges." Yet during the past year two licenses were issued to men who did not fulfil the statutory requirement.

Until the new law becomes effective, Massachusetts will continue to admit to examination the holder of a diploma from any legally chartered school. Ninety-six, therefore, from substandard schools have been licensed in this state.

Texas requires standards "as high as those adopted by the better class of medical schools" but nevertheless granted three licenses to persons who could not possibly satisfy the law.

The Virginia law specifies the standard of the American Medical Association or the American Institute of Homeopathy. One physician licensed in 1917 lacked such qualifications.

Nine states which leave it to the discretion of the board to determine whether medical schools are "reputable" or "satisfactory" nevertheless admitted to practice 130 graduates of unrecognized schools.

Laws regulating practice are designed to protect the public from the dangers of ignorance and incompetence masquerading as medical knowledge and skill. In spite of these laws we find that 232 licenses have been granted to those who failed to satisfy any reasonable standard of professional training. Do the laws really protect the people?

FEDERAL FOOD AND DRUG BILL ADVANCED

The Committee on Interstate and Foreign Commerce of the House of Representatives reported to the House, April 14, a bill to prohibit, in interstate and foreign commerce and within the District of Columbia, commerce in adulterated and misbranded foods, drugs, diagnostic and therapeutic devices and cosmetics. This bill was offered as a substitute for what was left of the Copeland food, drugs, devices and cosmetics bill, S. 2, passed by the Senate March 9, 1937, after the House committee had stripped it of all provisions relating to advertising. The advertising provisions of the Copeland bill have already been incorporated, in a modified form, in the Wheeler-Lea Federal Trade Commission Act,¹ approved March 21, 1938.

Like the Wheeler-Lea Federal Trade Commission Act, the bill reported by the committee is a composite of provisions to protect the consumer against ignorant and unscrupulous manufacturers and dealers, and of provisions to protect manufacturers and dealers against consumers and law enforcement officers. It may be questioned whether the balance is in favor of the consumer or of the manufacturer and dealer. Foods and cosmetics are covered by the regulatory provisions of the bill more effectively than are drugs and diagnostic and therapeutic devices. The committee itself points out that the Food and Drugs Act of 1906 is greatly weakened by the absence of authoritative definition and standards of identity for foods. It proposes, therefore, that the Secretary of Agriculture be authorized to promulgate regulations fixing definitions and standards of identity for foods. It believes that this will meet the demands of the legitimate food industry, prevent chiseling operations on the part of some manufacturers and insure fair dealing in the interest of the consumer.

¹ States Registering Other than Graduates of Approved Medical Schools—1937 this issue p. 1358

¹ Public Law No. 447 75th Cong. discussed in editorial in THE JOURNAL April 2, 1938 p. 1112

However, the committee has not written into its bill a single mandatory definition or standard for a drug or a diagnostic or therapeutic device nor authorized any officer or agency of the government to fix any definition or standard. So far as mandatory definitions and standards for drugs are concerned, the committee's bill is weaker than the law now in force, for it recognizes definitions and standards established by the Homeopathic Pharmacopeia of the United States and supplements to it and to the United States Pharmacopeia and the National Formulary, none of which are now recognized as authorities.

The bill reported by the committee retains the provisions of the Copeland bill that propose to authorize the Secretary of Agriculture to require by regulations that the labels of foods that are represented as having special dietary uses contain such information concerning their vitamin, mineral and other dietary properties as may be necessary to inform purchasers fully as to their value for such uses. It retains, too, the provisions of the Copeland bill authorizing the temporary control of any class of food, originating within a stated area, by a permit system to be established by the Secretary of Agriculture as occasion requires, so as to permit what might be termed a quarantine against foods liable to be contaminated by dangerous micro-organisms, such as *Bacillus botulinus*. Requirements as to disclosures on the labels of essential ingredients of composite foods are to be waived in favor of proprietary foods, if the committee's bill is enacted, whenever disclosure would give competitors information they could not otherwise obtain, if such ingredients have been disclosed to the Secretary of Agriculture.

The committee has incorporated in its bill provisions designed to prevent danger from the untimely introduction of new drugs. It proposes that no new drug shall be introduced into interstate and foreign commerce or in commerce in the District of Columbia unless an application, filed with the Secretary of Agriculture as required by law, is "effective with respect to such drug." A "new drug" is defined as—

(1) Any drug the composition of which is such that such drug is not generally recognized among experts qualified by scientific training and experience to evaluate the safety of drugs, as safe for use under the conditions prescribed, recommended, or suggested in the labeling thereof except that such a drug not so recognized shall not be deemed to be a 'new drug' if at any time prior to the enactment of this Act it was subject to the Food and Drugs Act of June 30 1906, as amended and if at such time its labeling contained the same representations concerning the conditions of its use or

(2) Any drug the composition of which is such that such drug, as a result of investigations to determine its safety for use under such conditions has become so recognized but which has not otherwise than in such investigations, been used to a material extent or for a material time under such conditions.

The exception in subparagraph 1 is apparently to cover secret ingredients in "patent" and proprietary medicines, such as a qualified expert would be unwilling to class as safe. Determination of the safety or danger of any new drug is to be based not on original investi-

gation by the Secretary of Agriculture but on data submitted by the applicant. If the secretary does not reject an application within sixty days after it is filed, it becomes effective as justification or excuse for the commercial distribution of the drug unless the secretary in writing claims an extension of time. In any event, he must reject an application within 180 days from its filing, if he rejects it at all, and if he does not it becomes "effective." The bill proposes that the secretary be authorized to promulgate regulations to permit the distribution of new drugs among qualified experts for the purpose of investigation, without being subject to the restrictions imposed on their distribution generally.

Drugs intended for use by man are to be labeled "Warning—May be habit forming," if they contain alpha eucaine, barbituric acid, beta-eucaine, bromal, cannabis, carbromal, chloral, coca, codeine, heroin, morphine, opium, paraldehyde, peyote or sulfonylmethane or any chemical derivative of any such substance, which derivative has been found by the Secretary of Agriculture to be habit forming and so designated. Drugs dispensed on prescriptions of physicians, dentists and veterinarians, however, need not be so labeled and are exempted from such labeling if marked not to be refilled or if refilling is forbidden by law. If a drug is fabricated from two or more ingredients and is marketed under a name not recognized in an official compendium, its label need not bear the common or usual name of each active ingredient if such ingredients have been fully and correctly disclosed to the Secretary of Agriculture or if the drug is dispensed on the written prescription of a physician, dentist or veterinarian.

If the bill is enacted, its provisions will be enforced through cautionary notices, injunctions, seizures and prosecutions. The Secretary of Agriculture is expressly relieved from the duty of instituting proceedings against any one if he believes that the public interest will be served by a written notice or warning. Furthermore, no violation of the act may be reported to any United States attorney for the institution of criminal proceedings until the offender has been given an opportunity to present his views with regard to the contemplated proceeding. No person is to be fined or imprisoned for having received in interstate or foreign commerce any adulterated food, drug, device or cosmetic, and delivered it, if he did so "in good faith," or in commerce in the District of Columbia, if he discloses to the secretary, on request, the name and address of the person from whom he purchased it and gives copies of all pertinent papers relating to the transaction.

The bill reported by the House Committee on Interstate and Foreign Commerce, like the Copeland bill, proposes to strip the Secretary of the Treasury and the Secretary of Commerce of all authority they now have with respect to the promulgation of regulations for the enforcement of the Food and Drugs Act of 1906, except such as the Secretary of the Treasury has over

imports and exports. All other regulatory authority is to be vested in the Secretary of Agriculture. Every United States district court in the country, however, of which there are eighty-three, is given the right under certain conditions not only to declare a regulation promulgated by the secretary to be unconstitutional and void and to restrain its enforcement but to direct the secretary to take such action as the court deems proper in furtherance of justice. This seems to propose an innovation in our judicial system, vesting the district courts with authority to direct an executive officer as to what regulations he shall make. It is likely to prove an obstacle to the early enactment of legislation. Otherwise, the provisions of the bill relating to the procedure to be followed in the promulgation of regulations, borrowed in principle from the Copeland bill, seem to constitute a wholesome restraint on administrative legislation.

Current Comment

OSTEOPATHY OR MEDICINE

Before a select committee of the House of Lords a few years ago the British osteopaths sought to be included in the Medical Register but soon withdrew their request. According to their own witnesses, osteopathy is something independent of medicine which does not rely on the medical sciences for diagnosis and which has no need of any chemical agents in its treatment. In the United States, however, the osteopaths have more and more invaded the practice of medicine. There are now at least half a dozen states in which they are granted unrestricted licenses to practice medicine and surgery, and in many other states similar privileges are being demanded. Obviously, if osteopaths wish to practice medicine they should be willing to conform to the same educational requirements as are demanded of all others who are granted this privilege. Their schools should conform to the same standards. The refusal, however, of the osteopathic schools to permit inspection by the Council on Medical Education and Hospitals inevitably suggests that the claim that these schools teach medicine in all its branches would not bear investigation. Osteopathy is on the spot! Does it, or does it not, include medicine?

SENATOR WAGNER'S RESOLUTION FOR THE STUDY OF MEDICAL CARE

On April 11, Senator Wagner of New York introduced into the Senate of the United States a resolution (S. Res. 265) which was referred to the Committee on Education and Labor. The resolution proposes to authorize the expenditure of \$50,000 to be used by a committee of three senators in making a general study, investigation and analysis of the adequacy and cost of medical care in relation to income and ability to pay, and also of ways and means to maintain and improve the health of the people of the United States. The resolution seems to be written right out of the proposals of the so-called Committee of 430 physicians.

Thus the resolution suggests that the committee in its investigation include but not limit itself to the following five points, which, for comparison, are placed parallel to the proposals of the Committee of 430.

SENATOR WAGNER'S FIVE POINTS

1 Expansion of federal aid to and cooperation with state and local public health services and the coordination of such services with the work of private institutions and groups.

2 Extension of governmental aid by cooperation of state and federal governments, in support of (a) adequate medical care for the medically indigent, (b) medical education, research, investigations and procedures for raising the standards of practice in preventive and curative medicine, and (c) private institutions and groups rendering hospital, laboratory, diagnostic and consultative services to the medically indigent.

3 Operation of existing public and private health insurance or group health systems, with particular reference to the manner in which they were instituted and are now functioning, the method of financing, the nature and extent of benefits, and the results achieved.

4 Utilization of professional experts in the planning, direction and execution of the foregoing measures.

5 Any other subject, matter, or thing adjudged by the committee to be relevant or germane to the foregoing subjects of inquiry.

PROPOSALS OF COMMITTEE OF 430

1 That the first necessary step toward the realization of the above principles is to minimize the risk of illness by prevention.

7 That public health services, federal, state and local should be extended by evolutionary processes.

2 That an immediate problem is provision of adequate medical care for the medically indigent, the cost to be met from public funds (local and/or state and/or federal).

3 That public funds should be made available for the support of medical education and for studies, investigations and procedures for raising the standards of medical practice. If this is not provided for, the provision of adequate medical care may prove impossible.

5 That public funds should be made available to hospitals that render service to the medically indigent and for laboratory and diagnostic and consultative service.

6 That in allocation of public funds, existing private institutions should be utilized to the largest possible extent and that they may receive support so long as their service is in consonance with the above principles.

8 That the investigation and planning for the measures proposed and their ultimate direction should be assigned to experts.

The Principles and Proposals of the Committee of 430 grew out of the report of the American Foundation Studies in Government. The resolution goes far beyond that report, however, in proposing to have the senators conduct a complete investigation of everything pertaining to medical education and medical service in a period of a few months, and with the expenditure of \$50,000. The Committee on the Costs of Medical Care spent about a million dollars over a term of five years and assembled a considerable staff for the purpose of its study. The Commission on Medical Education spent a small fortune over a period of three years. Five

National Health Survey employed 7,000 WPA workers and indulged in a tremendous expenditure to reach certain figures, which some statisticians consider inconclusive and doubtful. Right now the American Medical Association is using all the doctors of the country in an investigation of medical needs, with a view to having local determination as to how those needs may be met with the facilities available in each community.

HOW MANY TIMES IS ENOUGH?

In determining the fitness of candidates for medical licensure, the state boards for various reasons rely almost exclusively on written examinations. Now it is obvious that a written examination cannot measure skill. It is, at best, a weak instrument for the selection of those who may be safely granted the right to practice medicine. Surely the examining procedure is unnecessarily degraded when a candidate is permitted to repeat the examination after a dozen successive failures. Massachusetts licensed seventy-seven and New York 189 who had previous failures. In the former state two licensees had each failed thirteen times, four ten times, three nine times, two eight and two seven times each, a total of 123 failures among thirteen candidates. In these two states, 101 physicians were licensed after two or more failures. Is it not time for the people to wake up and put an end to this farce? If the purpose of our professional laws is to safeguard the public, they should be so amended as to impose a reasonable limit to the number of examinations a candidate may attempt.

NEW SEROLOGIC TESTS FOR SYPHILIS

The publications of the Committee on the Evaluation of Serologic Tests for Syphilis indicate that all too frequently both complement fixation and flocculation tests are carried out at a level of efficiency below that of which the tests are inherently capable. It is alarming that some commercial concerns are offering for sale to general practitioners relatively new and unestablished serologic test outfits containing antigen and other materials. The promoters claim that these methods may be carried out by the practitioner in his office, are suitable for rapid diagnostic work with whole blood and with spinal fluid and are sufficiently accurate to guide any physician in the treatment of his patients with syphilis. The fact that the antigens for these methods are crude or that they may deteriorate rapidly is not mentioned. Neither is it pointed out that the dye materials incorporated in the antigens are useless to a trained serologist and will be equally valueless to one not familiar with the interpretation of flocculation reactions. Warning is not given of the danger which is always present in serologic procedures carried out with whole blood or of the complete reversal which inactivation may induce. Nor is it admitted that these methods have had only a limited practical test in hands other than those of the originators. Furthermore, a most grievous omission is the failure to recommend the use of positive and negative control serum as guides in the interpretation of the test. The care of glassware, the concentration and pH of the salt

solution and many other factors requisite for trustworthy serologic results are omitted from the instructions. Thus, active commercial promoters may place in the hands of the individual physician everywhere a diagnostic function which is acceptable as efficient only when performed in laboratories adequately equipped and staffed by trained personnel. The claims for these technics are based on inadequate experience and the procedures themselves are open to criticism on many technical grounds. The science of serology has not as yet progressed to a degree of simplicity at which the detection of syphilis may be placed on a basis comparable to the detection of albumin in the urine. It is difficult to see how any premature steps in this direction can do other than work to the detriment of the patient with syphilis.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

Personal—Dr. Bernard L. Wyatt, Tucson, has received a medal from the Comité National de Défense contre la Tuberculose in France in appreciation of his tuberculosis work during the World War.

Society News—A symposium on the diagnosis of bladder neck obstruction was presented before the Maricopa County Medical Society in February; the speakers were Drs. John W. Pennington, Hilary D. Ketcherside, Howard M. Purcell and Mihajlo Matanovitch. Dr. Merrivether L. Day spoke on "Carcinoma of the Prostate." The society was addressed at a special meeting in February by L. E. Detrick, research assistant, University of California, Los Angeles, on "Citrin-Culture in Its Relation to Health."

ARKANSAS

District Meetings—At the semiannual meeting of the Second District Medical Society, at Batesville, April 11, the speakers were Drs. John N. Compton, Little Rock, on "Acute Infectious Diseases," and James E. Jones, Little Rock, "Diarrheas." Dr. Benjamin F. Turner, Memphis, Tenn., addressed a dinner session on "Medicine as a Vocation."—The Third District Medical Society was addressed at its semiannual meeting in Hazen April 7 by Drs. Daniel H. Autry, Little Rock, on "Coronary Artery Disease," William D. Mims, Memphis, "Practical Aspects of Infant Nutrition and Nutritional Disorders," Paul Mahoney, Little Rock, "X-Ray Diagnosis of Non-opaque Foreign Bodies in the Air Passages," John S. Agar, Little Rock, "Diagnostic Bronchoscopy," and "Foreign Bodies in the Food and Air Passages," and Joshua Harley Harris, Memphis, "The High Spots of Sinus Trouble in the Practice of Medicine."

CALIFORNIA

University News—At the sixth clinical congress of the Alumni Association of the College of Medical Evangelists, Los Angeles, March 20, Drs. John E. Gregory spoke on "Diarrhea and Salt Metabolism," Dorrell G. Dickerson, "Surgical Treatment of Hypertension," William H. Olds, "Treatment of Acute Cholecystitis," and Donald C. Collins, "Indications for the Use of Papaverine Hydrochloride in Arterial Emboli."

Carbon Monoxide in Motor Vehicles—The industrial hygiene service of the state department of public health in cooperation with the state highway patrol has been conducting tests on motor vehicles to determine the amount of carbon monoxide to which drivers are exposed. Of 688 drivers tested in the preceding month according to the bulletin of the state department of health, February 26, the drivers of twenty-four vehicles or 3.47 per cent were found to have been exposed to dangerous concentrations of carbon monoxide while operating vehicles on the highway. The investigations are being

conducted by Dr John P Russell, Berkeley A patrolman signals the driver to stop and the physician then accompanies him for a five minute run, testing the floor board of the truck with special instruments

COLORADO

Annual Spring Clinics—The Pueblo County Medical Society will present its fifth annual spring clinics in Pueblo April 29-30 The guest speakers on the program will include

Dr Carl H Gellenthien Valmore N M, Diagnosis and Differential Diagnosis of Pulmonary Tuberculosis
Dr Stuart W Harrington Rochester Minn, Diagnosis and Treatment of Various Types of Diaphragmatic Hernia
Dr George Gill Richards Salt Lake City Hypothyroidism Short of Myxedema
Dr Edward G Billings Denver Symptoms and Diagnosis in General Medicine

At the annual banquet Friday evening, James E Gheen, New York humorist, will be the guest

DISTRICT OF COLUMBIA

Personal—*Parents Magazine* recently awarded a medal to Dr Thomas Parran, surgeon general, U S Public Health Service, for outstanding service to children The citation praised Dr Parran's work in control of venereal diseases—Dr Robert A Hare, Santa Barbara, Calif, has been appointed medical director of the Washington Sanatorium and Hospital, Takoma Park

FLORIDA

New Director of Laboratories—Dr James N Patterson, assistant professor of pathology, University of Cincinnati College of Medicine, Cincinnati, has been appointed director of laboratories of the state department of health, Jacksonville, to succeed the late Dr Paul Eaton Dr Patterson graduated at the University of Cincinnati College of Medicine in 1929

Society News—The Duval County Medical Society was addressed in Jacksonville March 1 by Drs Stanley Erwin on "Differential Diagnosis of Painless Jaundice" and Frederick J Waas, "Indications for Surgery in Gallbladder Disease"—At a meeting of the Jackson County Medical Society in Marianna recently Dr Rudolph Bell, Thomasville, Ga, presented a paper on "When to Operate for Urinary Calculi"

GEORGIA

The Carter Memorial Laboratory—The Henry R Carter Memorial Laboratory of the U S Public Health Service, Savannah, was formally dedicated February 8 The laboratory, designed for the study of malaria control, is named in honor

Carter Memorial Laboratory

of the late Dr Henry Rose Carter Dr Thomas H D Griffiths, senior surgeon, U S Public Health Service, has been in charge of the laboratory since it was opened in 1937 Situated on a five acre tract owned by the city

of Savannah, the building was erected by city and WPA funds while the equipment, costing about \$20,000, was financed by the public health service Dr Griffiths delivered the dedicatory address and the response was given by Dr Henry R Carter Jr, Birmingham, Ala, son of the late Dr Carter The senior Dr Carter graduated as a civil engineer from the University of Virginia in 1873 and as a doctor of medicine from the University of Maryland School of Medicine in 1879 He entered the U S Public Health Service as assistant surgeon For many years he was connected with work on yellow fever He inaugurated a quarantine system in Cuba in 1899 and from 1904 to 1909 was director of hospitals in the Canal Zone He was made assistant surgeon general in 1915 In 1914 Dr Carter's interest turned to the study of malaria and he is credited with conducting the first campaign against malaria in this country He went to Central and South America as a member of the Rockefeller Foundation Yellow Fever Commission in 1917, was in charge of malaria work 1917-1918, was sanitary adviser to the Peruvian government 1920-1921 and was a member of the Yellow Fever Commission of the International Health Board from 1920 until his death in Washington, Sept 14, 1925, aged 73

Personal—Dr Russell H Oppenheimer, dean and professor of medicine, Emory University School of Medicine, Atlanta, has been appointed acting superintendent of Grady Hospital, effective March 15 Dr Oppenheimer succeeds Mr John B Franklin, who resigned to accept a similar position at the

John D Archbold Memorial Hospital, Thomasville—Dr Harris M Branham, Brunswick, was recently guest of honor at a dinner to observe his completion of fifty years in the practice of medicine

IDAHO

Personal—Dr Samuel Weissross, Boise, assistant director of public health, has taken charge of industrial hygiene activities and of medical statistics—Drs Albert B Pappentagen, Orofino, and John Harry Einhouse, Moscow, addressed the North Idaho Medical Society, Lewiston, January 20 on back injuries and cutaneous diseases, respectively

ILLINOIS

Central States Industrial Meeting—The nineteenth annual meeting of the Central States Society of Industrial Medicine and Surgery will be held in Springfield May 1 in conjunction with the annual convention of the Illinois State Medical Society Speakers will include

Dr Clarence O Sappington Medicolegal Aspects of Occupational Diseases
Dr James A Britton Recognition of Early Tuberculosis in Industry
Dr William D McNally The Industrial Solvents
Dr Cleveland J White Skin Infection in Industry with Special Reference to the Value of Patch Tests

One session, in conjunction with the surgical section of the state medical society, will be addressed by Drs Chester C Guy and Philip H Kreuscher on "Traumatic Lesions of the Spleen" and "Injuries of the Right Upper Abdominal Quadrant" All speakers are from Chicago

Chicago

Courses on Obstetrics and Pediatrics—A series of weekly courses on obstetrics and pediatrics will begin July 3 at the Research and Educational Hospital, University of Illinois College of Medicine, to continue through July and August The state department of health is offering these courses in cooperation with the educational committee of the Illinois State Medical Society through the facilities of the University of Illinois The courses in obstetrics will include outpatient dispensary clinics, special lectures, manikin course and home deliveries in the outpatient service, in addition there will be round table discussions Ward walks and special lectures and service in the outpatient department will make up the courses in pediatrics Dr Harold H Hill, associate in the department of obstetrics and gynecology, University of Illinois College of Medicine, and field consultant in maternal and child hygiene in the state department of public health, is in charge of arrangements

Society News—Dr Erwin O Strassmann, Rochester, Minn, among others, addressed the Chicago Gynecological Society April 15 on "Technic and Results of Routine Fetal Electrocardiography During Pregnancy"—The Chicago Pathological Society was addressed April 11, among others, by Drs George J Rukstinat, Chicago, and Charles G Weller, Aurora, Ill, on "Spindle Cell Sarcoma of the Prostate Gland"—At a meeting of the Chicago Council of Medical Women April 13, Drs Helen Holt and Bertha A Klien spoke on "Role of Vitamins in Ophthalmology" and "Ophthalmoscopic Diagnosis and Differential Diagnosis of Hypertensive and Renal Disease" respectively—The Chicago Roentgen Society was addressed April 14, among others, by Kenneth Corrigan Ph D, Harper Hospital, Detroit, on "Artificial Radioactivity" and Robert S Landauer Ph D, "New Types of High Voltage Generators"—Dr Philip S Carney, among others, addressed the Chicago Tuberculosis Society April 14 on "Fallacies in the Handling of Pneumococcus Cases"—At a meeting of the Chicago Society of Allergy April 18 the speakers were Dr Samuel J Zakon and Samuel J Taub on "Inhalation of Horse Dander and House Dust as Etiologic Factors in Atopic Dermatitis" and Simon S Rubin and Theodore B Bernstein "Effect of Volume on Absorption of Antigen"—Dr Wilhelm Drescher Vienna will address the Chicago Society of Internal Medicine April 25 on "The Cardiac Aneurysm Its Diagnosis and Prognosis"

IOWA

State Medical Meeting at Des Moines May 11-13—The eighty-seventh annual session of the Iowa State Medical Society will be held in Des Moines May 11-13 at the Hotel Fort Des Moines under the presidency of Dr Edward M Myers, Boone The guest speakers will include

Dr Cyrus C Sturgis Ann Arbor Mich Diseases Associated with Changes in the Red Blood Cells
Dr Everts A Graham St Louis Thoracic Surgical Diseases
Dr Otto Jason Dixon Kansas City Mo The General Practitioner's His Own Otolologist
Dr Edward N Cook Rochester Minn Urinary Antiseptics
Dr Harry E Mock Chicago Treatment of Craniocelebral Injuries

Sectional conferences will be held Wednesday and Thursday afternoons and a symposium on operative obstetrics will be held Friday morning with the following speakers: Drs. Everett D. Plass, William F. Mengert, John H. Randall, all of Iowa City; Lawrence E. Kelley, Des Moines; Howard A. Weis, Davenport; Otto N. Glesne, Fort Dodge; and Roy E. Crowder, Sioux City. Dr. Kenneth L. Johnston, Oskaloosa, will be toastmaster at the annual banquet Thursday evening. Rev. Alphonse M. Schwitalla, S.J., dean, St. Louis University School of Medicine, will deliver an address Friday on medical economics. The State Society of Iowa Medical Women will hold its forty-first annual meeting May 11; the speakers will include Drs. Irene A. Koenek, Halstead, Kan., on goiter; Cora W. Negus, Keswick, epidemic encephalitis; and Rosabell Butterfield, Indianola, alcohol in relation to the human system. The Woman's Auxiliary to the state medical society will meet May 11-12.

KANSAS

Society News—The Bourbon County Medical Society was addressed in Fort Scott February 14 by Drs. Victor H. Bergmann and Frank M. Postlethwaite, both of Kansas City, Mo., on "Common Dysfunction of the Ovary in Endocrinology" and "Ambulatory Treatment of Diseases of the Rectum" respectively. Dr. Carl O. Rice, Minneapolis, discussed "The Injection Treatment of Hernia" before the Wyandotte County Medical Society, Kansas City, April 19.

University News—The Hixon Laboratory for Medical Research at the University of Kansas School of Medicine, Kansas City, has been completed at a cost of \$65,000. The laboratory is designed to encourage research work in all departments of the medical school and provides facilities for advanced study in the laboratory and clinical sciences. A short time ago a gift of \$45,000 was received by the university to be used for the erection of two additional floors to the building. An original gift of \$20,000 and a PWA grant financed the construction of the laboratory.

Venereal Disease Programs—The first of a series of two day graduate courses on venereal disease control to be given in all of the twelve councilor districts of the state opened in Hiawatha March 24-25 under the auspices of the state board of health and the Kansas Medical Society. Following is the schedule of the courses, which are being financed by the U. S. Public Health Service: Hays, April 4-5; Colby, April 6-7; Emporia, April 13-14; Salina, April 18-19; Hutchinson, April 25-26; Kinsley, May 2-3; Ottawa, May 23-24; Parsons, June 2-3; and Concordia, June 14-15. Dr. Arthur D. Gray, Topeka, is giving the lectures, which are open to all licensed physicians in the state.

LOUISIANA

Society News—The Eighth District Medical Society was addressed in Marksville March 16 by Drs. Arthur A. Caire Jr. on "Obstetrical Anomalies as Handled in the Home"; Idys M. Gage, "Infections of the Hand"; Julian Graubarth, "Summer Diarrhea in Children"; and Stanford Chaille Jamison, "Diseases of the Heart." All are from New Orleans.

Medicolegal Symposium—The Orleans Parish Medical Society, New Orleans, sponsored a medicolegal symposium March 28 to consider "Relation of the Physician and Surgeon to the Administration of Justice." The following participated:

Hon. Harold A. Moise, judge, civil district court for Orleans Parish.
Hon. William J. O'Hara, judge, criminal district court for Orleans Parish.
Hon. Archibald T. Higgins, associate justice, supreme court of Louisiana.
Hon. George J. Gulotta, assistant district attorney, Orleans Parish.
St. Clair Adams, Esquire, attorney for the Louisiana State Medical Society.

State Medical Meeting in New Orleans May 2-4—The Louisiana State Medical Society will hold its annual meeting in New Orleans May 2-4 under the presidency of Dr. Charles M. Horton Franklin. The guest speakers will be Drs. James Barrett Brown, St. Louis, on "Care of Compound Injuries of the Face"; Virgil S. Counsellor, Rochester, Minn., "Gynecological Problems Occurring in the Reproductive Period"; and Ray M. Bulveat, Oklahoma City, "Common Allergic Manifestations Encountered by the General Practitioner." Louisiana physicians included on the program are:

Dr. George J. Taquino, New Orleans, "The Value of Broncho copy in Bronchiogenic Carcinoma."
Dr. Isadore Cohn, New Orleans, "Burns and Unolved Problems."
Dr. Stanford Chaille Jamison, New Orleans, "Pulmonary Atelectasis."
Dr. Arthur A. Herold, Shreveport, "Inulin Allergy with Report of Severe Case and Successful De-intoxication."
Dr. Stonewell J. Phillips, Pineville, "Insulin and Metrazol Therapy in Dementia Praecox."

The section on public health and sanitation will present a symposium on venereal diseases with Drs. James A. Coleman, Edgar Burns, and James K. Howles, New Orleans, as speakers.

MAINE

Society News—Dr. Roland B. Moore, Portland, addressed the Androscoggin County Medical Society recently on obstetrics, speakers before the society March 17 included Drs. Charles W. Steele and Vincent H. Beeaker, Lewiston, on coronary thrombosis and extrauterine pregnancy, respectively. Dr. Oramel E. Haney, Portland, discussed diagnosis and treatment of the more common skin diseases before the Portland Medical Club March 1. Among others, Dr. William J. O'Connor addressed the Kennebec County Medical Association in Augusta, March 17, on "Generalized Carcinomatosis of the Abdomen" and "Glioma of the Spinal Cord." Dr. Edwin H. Place, Boston, discussed contagious diseases. Dr. Henry R. Viets, Boston, addressed the Cumberland County Medical Society April 22 on "Acute Lymphocytic Meningitis and Other Virus Diseases of the Nervous System."

MASSACHUSETTS

University News—Dr. Henry A. Christian gave the annual lecture of the Sir William Osler Society of Tufts College Medical Society, Boston, March 18, his subject was "The Fruition of the Clinician." Dr. Reginald Fitz, lecturer on the history of medicine and university marshal, Harvard University Medical School, Boston, delivered the George W. Gay Lecture on Medical Ethics at the university March 15; his paper was entitled "A Few of the Rules."

Course in Occupational Dermatoses—The Harvard School of Public Health, Boston, will conduct a course in occupational dermatoses in May. Lectures will be given on the clinical manifestations, etiologic factors, diagnosis, treatment, insurance and legal aspects. Clinics will be held at the Massachusetts General Hospital and various insurance companies. Visits to factories will be arranged so that students may study industrial processes and preventive measures. The number will be limited to ten. Further information may be obtained from the Harvard School of Public Health, 25 Shattuck Street, Boston.

MICHIGAN

Physician Honored—A bronze plaque showing the profile of Dr. Colin D. Munro, Jackson, was presented to W. A. Foote Memorial Hospital March 15 in his honor and to mark the dedication of the recently completed electric call and signal system at the institution. A member of the staff of the hospital, Dr. Munro was president of the Jackson County Medical Society in 1913 and has served as chairman of the surgical section of the Michigan State Medical Society. He has practiced in Jackson since 1900.

New Health Unit—Dr. Clarence D. Barrett, East Lansing, director of the bureau of communicable diseases of the state department of health, has been placed in charge of a newly created full time health unit in Ingham County. The unit was to begin operation April 1. Dr. Barrett has served as health officer of Wayne and Loran counties and the city of Mansfield, Ohio. He has been associated with the Michigan department of health since March 1931. Dr. Filip C. Forsbeck, for six years assistant director of the bureau of communicable diseases of the state department of health, will succeed Dr. Barrett as director.

Society News—Dr. Cyril K. Valade, among others, addressed the East Side Physicians Association, Detroit, March 17, on "Cutaneous Manifestations of the Eruptive Fevers." Dr. Sumner L. S. Koch, Chicago, addressed the medical section of the Wayne County Medical Society, Detroit, March 14 on "Injuries of the Hand and Forearm." Dr. Don W. Gudakunst, state health officer, Lansing, discussed "The County Health Unit" at a meeting of the Washtenaw County Medical Society, Ann Arbor, March 8. Dr. Oliver W. Lohr, Saginaw, was recently chosen president-elect of the Michigan Pathological Society at a meeting in Ann Arbor and Dr. Ruth C. Wanstrom, Ann Arbor, was installed as president. Dr. William L. Brosius, Detroit, is the secretary.

MISSOURI

Conservation of Eyesight—The St. Louis County Medical Society and the county health department are sponsoring a program for conservation of eyesight. Public lectures are being given together with a showing of the talking sound film "The House of Vision." Members of the committee in charge of the program include Drs. Clyde P. Dyer, St. Louis, chairman; Alvin D. Calhoun, Leslie C. Drews, Alonzo G. Hobbs and Clarence L. Hobbs, St. Louis; William H. Bailey and Walter A. Zentler, Jennings.

State Medical Meeting in Jefferson City—The eighty-first annual meeting of the Missouri State Medical Association will be held in the House Chamber, Capitol Building, Jefferson City, May 2-4, under the presidency of Dr Dudley S Conley, Columbia. The speakers will include

Dr John H J Upham, Columbus Ohio, President American Medical Association Clinical Significance of Gastric Motility in the Human Subject

Dr George M Curtis, Columbus Ohio The Iodine Metabolism in Thyroid Disease

Dr Palmer Findley, Omaha Puerperal Sepsis

Dr Daniel L Sexton, St Louis Intermenstrual Pain

Dr Jacob G Probst, St Louis Diastase Test as an Aid in the Diagnosis of Perforated Peptic Ulcer

Dr John McLeod, Kansas City The Eyes in Congenital Syphilis

Dr Dan G Stine, Columbia Effect of Work on the Heart

Dr Orval R Withers, Kansas City Allergy Due to Molds

Dr Edward T Gibson, Kansas City, Traumatic Psychosis

Dr Radford F Pittam, Kansas City Carotid Denervation in Epilepsy

Dr Anthony B Dry, St Louis, Myasthenia Gravis Methods of Treatment, with Report of a Case

Dr Arthur Lloyd Stockwell, Kansas City, Factors in Determining the Management of Prostatic Enlargement

Dr August A Werner, St Louis Obesity and Its Treatment

A round table will be held by the maternal welfare committee at which Dr Findley will present a "Critique of Submitted Maternal Death Reports." Entertainment will include golf, skeet and bowling tournaments and a stag dinner Monday evening with the Cole County Medical Society as host.

NEBRASKA

Society News—Judge E B Chappell, Lincoln, addressed the Lancaster County Medical Society, Lincoln, March 1, on "The Doctor in Court" and Dr Edna W Schrick on "Functional Dysmenorrhea."—At a meeting of the Madison Six County Medical Society in Norfolk March 1 the speakers, all of Omaha, were Drs Esley J Kirk, on nephritis, Harrison A Wigton, minor psychosis, Abraham S Rubnitz, pathology of blood, and Robert D Schrock, who gave a fracture demonstration.—Drs Harry H Everett and Harry E Flansburg, Lincoln, addressed the Fillmore and Saline County Medical Society, Crete, March 3, on pulmonary tuberculosis and pulmonary embolism respectively.—At a meeting of the Southwest Nebraska Medical Society in McCook March 17, the speakers, all of Denver, were Drs James E Russell Jr on "Jaundice in the Newborn", Clarence B Ingraham, "Embryonal Tumors of the Ovary," and William C Black, "Pathology Relative to Ovarian Embryonal Tumors."

NEW YORK

Report of Cancer Commission—The commission appointed in 1937 to survey the prevalence of cancer in the state and facilities for treatment has made a report to the governor and the legislature and recommended continuation of the work for another year to permit completion of its studies. Chief of the commission's recommendations were reorganization and extension of the division of cancer control in the state department of health and changes in the public health law to make cancer a reportable disease. Among other points brought out in the report were that facilities for diagnosis of cancer are lacking in hospitals of less than 100 beds, facilities for roentgen treatment are insufficient to carry the minimum treatment load, radium is poorly distributed especially in the central area of the state, accommodations for terminal care of the cancer patient are inadequate for the indigent and upstate New York is suffering from a serious deficiency in treatment facilities. The commission recommended that, at least for the present, development of cancer control be away from centralization and in the direction of improved care in already existing local public and private hospitals. The division of cancer control is under the direction of Dr Burton T Simpson, director of the State Institute for the Study of Malignant Diseases, at Buffalo. Under the commission's recommendations an office would be set up for the director of the division with an adequate and competent staff and an initial appropriation of \$50,000 a year. The legislature appropriated \$15,000 for the commission's work during the coming year.

New York City

Harvey Lecture—Fred C Koch, Ph D professor of biochemistry, University of Chicago, delivered the seventh Harvey Lecture of the current series at the New York Academy of Medicine April 21 on "The Chemistry and Biology of Male Sex Hormones."

Annual Art Exhibit—The eleventh annual exhibition of the New York Physicians' Art Club will be held at the New York Academy of Medicine, 2 East One Hundred and Third Street, May 9-21. Paintings and work in the graphic and

plastic arts by members of the medical profession will be shown. Dr Henry A Bancel is president and Dr James R Gudger secretary of the club.

Personal—David H McAlpin Pyle was recently reelected president of the United Hospital Fund for the fourth successive term.—Dr Jacob J Golub, executive director of the Hospital for Joint Diseases, has been appointed by Governor Lehman to the Saratoga Springs Authority.—The William H Nichols Medal for chemical research was presented to Dr Phoebus A Theodore Levene of the Rockefeller Institute for Medical Research by the New York Section of the American Chemical Society at a dinner March 11. Announcement of the award was made in THE JOURNAL, Dec 11, 1933, p 994.—Dr Herman J Burman has been appointed director of the department of otolaryngology at the Harlem Hospital.

NORTH CAROLINA

Society News—A symposium on roentgen therapy was presented before the Buncombe County Medical Society, Asheville, March 21, by Drs Gibbons W Murphy, who discussed treatment of infections, John D MacRae, endocrine disorder and Seba L Whitehead, dermatology.—At a meeting of the Catawba Valley Medical Society, Lincolnton, March 13, the speakers were Drs Abner M Cornwell, Lincolnton, on "Dueticulitis of the Sigmoid Colon", Daniel N Stewart Jr Hickory, "The Clinical Value of Electroradiography," and Edward W Phifer, Morganton, "Surgical Problems."—Drs Ivan M Procter, Raleigh, and Coy C Carpenter, Wake Forest, addressed the Robeson County Medical Society March 3 on cancer of the breast.—Dr Ellis B Gray, Spartanburg S C, addressed the Rutherford County Medical Society in February on "Complications of Otitis Media."—Dr William B Dewar, Raleigh addressed the Johnston County Medical Society, Smithfield, in March on recent advances in medical therapy.

OHIO

New Executive Secretary in Toledo—Mr George W Cooley, Toledo, has been appointed executive secretary of the Toledo Academy of Medicine to succeed Mr Henry C Gerber Jr who resigned to become executive secretary of the Michigan State Dental Society. Mr Cooley is a graduate of the school of business administration of the University of Cincinnati. Mr Gerber had been with the academy since 1930.

Practitioners Honored—The Morrow County Medical Society sponsored a luncheon in honor of Dr Frederick E Thompson, Marengo, March 8 marking his completion of fifty years in practice.—Dr James Owen Howells Bridgeport was honored by the Belmont County Medical Society with a banquet in Bellaire, marking his seventy-fifth birthday February 17. Dr Howells described changes in medical practice during the past forty years, the society gave him a watch.

PENNSYLVANIA

Graduate Assembly—At the third graduate assembly of the year at Geisinger Memorial Hospital, Danville, April 7, the following were guest speakers: Drs Russell M Wilder, Rochester, Minn, on "Diagnosis and Treatment of Addison's Disease", Louis H Clerf, Philadelphia, "Mechanism of the Production of Physical Signs in Diseases of the Lungs," and Roy W Scott, Cleveland, "Clinical Aspects of Arteriosclerosis." The assemblies are sponsored by the Montour County Medical Society.

Philadelphia

Dr Rowntree Receives Strittmatter Award—Dr Leonard G Rowntree, director of the Philadelphia Institute for Medical Research at the Philadelphia General Hospital, received the annual Strittmatter Award a gold medal, of the Philadelphia County Medical Society at a meeting April 13 for his work on the thymus gland, cancer and arthritis. Dr Rowntree was appointed to the Philadelphia Institute in 1932. Previously he had been on the faculties of Johns Hopkins University, Baltimore, and the University of Minnesota at Minneapolis, and on the staff of the Mayo Clinic, Rochester, Minn. He was unable to attend the meeting because of illness. After the presentation the society heard a symposium on fever therapy given by Drs Frank H Krusen, Rochester, Minn, Joel J White, commander of the U S Naval Hospital at Philadelphia, Ferdinand Fetter and Truman G Schnabel. Dr Ferdinand Strittmatter, founder of the award, died the day after the presentation.

Society News—A symposium on sciatic pain was presented at a meeting of the Medical League of Philadelphia March 28, by Drs John B Roxby, Melvin W Thorner and Richard A Groff.—Speakers at a meeting of the Laennec Society

March 29 included Drs Samuel Bellet, on "Tuberculous Pericarditis" and Moses Behrend, Hodgkins Tumor of the Anterior Mediastinum and Anterior Chest Wall"—Dr John O. Bower addressed the Philadelphia Academy of Surgery April 4 on "When Should the Secondary Operation—Appendectomy—Be Performed Following Simple Drainage of an Appendiceal Abscess?" and Dr Robert H. Ivy on "Multiple Dentigerous Cysts, with Special Reference to Occurrence in Children of the Same Family"—Drs Arden Neil Lemon and Robert H. Ivy, among others, addressed the Philadelphia Laryngological Society April 5 on "Use of Undenatured Bacterial Antigen in Chronic Suppurative Sinusitis" and Tumors and Cysts of the Jaw" respectively—Dr Charles H. Best Toronto delivered a Hatfield Lecture of the College of Physicians of Philadelphia April 6 on Heparin and Thrombosis"—Drs John V. Blady and Alfred F. Hocker, New York, among others, addressed the Philadelphia Roentgen Ray Society April 7 on Sialography—Its Technic and Application in the Diagnosis of Diseases of the Parotid Gland"—Dr George S. Sprague White Plains, N. Y., among others, addressed the Philadelphia Psychiatric Society April 8 on "Proposed Classification of the Fields of Psychiatry."

VIRGINIA

McGuire Lectures and Centennial Symposium—The Stuart McGuire Lectures delivered annually at the Medical College of Virginia, Richmond will be combined this year with the fourth and final symposium celebrating the college's centennial, April 28-30. The program is as follows:

- Dr. George R. Minot, Boston: Etiology and Treatment of Anemia.
- Nutritional Deficiencies.
- Dr. Oliver H. Perry, Pepper, Philadelphia: A Survey of the So Called Hemolytic Anemias.
- Harvey E. Jordan, Ph.D., Charlottesville: Blood Formation in Birds with Special Reference to the Evidence for a Genetic Relation Between Lymphocytes and Erythrocytes.
- Dr. Nathan Rosenthal, New York: Leukemoid Reactions in Various Diseases.
- Dr. Alexis F. Hartmann, St. Louis: Some Clinical Studies of Subjects with Change in Their Acid Base Balance.
- Dr. Edward D. Churchill, Boston: Principles of Surgical Treatment of Hyperparathyroidism.
- Dr. Harvey B. Stone, Baltimore: Transplantation of Parathyroid Glands.
- Dr. Walter Bauer, Boston: The Nature of Degenerative Joint Disease (Hypertrophic Arthritis).

GENERAL

New Health Council Officers—Ira V. Hiscock, C.P.H., professor of public health, Yale University School of Medicine, New Haven, Conn., has been elected president of the National Health Council succeeding Dr. Donald B. Armstrong, New York. Dr. Charles Walter Clarke, New York, executive director of the American Social Hygiene Association was chosen vice president and Miss Dorothy Deming, New York, general director of the National Organization for Public Health Nursing, secretary.

Phillips Medal Awarded—The John Phillips Memorial Medal of the American College of Physicians was awarded to Dr. Harry Goldblatt, professor of experimental pathology, Western Reserve University School of Medicine, Cleveland at the annual session in New York, April 6 for his work on the production of experimental hypertension in animals. Dr. Goldblatt took his medical degree at McGill University Faculty of Medicine, Montreal in 1916. He has been a member of the Western Reserve faculty since 1924.

National Academy of Sciences—The spring meeting of the National Academy of Sciences will be held in Washington, D. C., at the academy's building April 25-26. Papers of medical interest will include:

- Kobley D. Evans and Robert S. Harris, Cambridge, Mass.: Studies in Radium Poisoning: The Metabolic Effects of Ingested Radium in Rats.
- Drs. Florence R. Sabin and Austin L. Joyner, New York: Cellular Reactions in Sensitization.
- Dr. Eugene F. DuBois and James D. Hardy, New York: Relationship of Humidity to Evaporation of Sweat.
- Harvey Fletcher, Ph.D., Flushing, N. Y.: The Mechanism of Hearing as Revealed Through Experiments on the Masking of Thermal Noise.
- Dr. James Ewing, New York, will deliver a lecture Tuesday evening on "The Public and the Cancer Problem."

Criteria for Accrediting of Nursing Schools—At a recent meeting of the executive committee of the committee on accrediting of the National League for Nursing Education it was decided to spend several months in developing criteria for the accrediting of nursing schools. Through data collected the committee expects to define certain principles that will serve as a guide in the making of surveys in the future and in the accrediting of schools. Application of the criteria thus developed are to be tested in different types of schools in various geographic areas. It was pointed out that eligibility for accrediting will be based on the characteristics of the

school as a whole and that no school will be rejected for one or two deficiencies, provided the general quality of performance is acceptable. The committee listed among its aims helping administrators to improve their schools, publication of a list of accredited schools to guide prospective students in their choice of schools of nursing and promoting interstate relationships in the professional registration of nurses.

Meeting of Gastroenterologists—The forty-first annual meeting of the American Gastro-Enterological Association will be held at the Hotel Claridge, Atlantic City, N. J., May 2-3. The speakers will include:

- Dr. Boris P. Babkin, Montreal, Canada: The Triple Mechanism of the Chemical Phase of Gastric Secretion.
- Dr. Earl D. Bond, Philadelphia: Psychiatric Contributions to the Study of the Gastrointestinal System.
- Dr. William C. MacCarty, Rochester, Minn.: Early Cancer of the Stomach and Its Clinical Significance.
- Dr. Warren H. Cole, Chicago: The Etiological Relationship of Lesions of the Cystic Duct to Cholelithic Disease.
- Dr. James B. Collip, Montreal, Canada: The Endocrines in Relation to the Gastrointestinal Tract.

Dr. William R. Houston, Austin, Texas, will address the annual banquet on "Our Relations with the Orient" and Christopher Morley, New York, author "Change Without Notice."

FOREIGN

Society News—An International Congress of Cosmobiology is being organized to be held in Nice, June 2-6, under the auspices of the Medical Society of Climatology and Hygiene of the Mediterranean Coast in cooperation with the International Association for the Study of Solar Radiation, Terrestrial and Cosmic. A detailed program will be sent on request to the president of the Mediterranean Coast medical society. Dr. Maurice Faure, 24 rue Verdi, Nice, France. Drs. William Bierman, New York, and Disraeli Kobak, Chicago, are physician members of an American committee established to support the congress. Information may be obtained from Miss Edna Minsky, 120 East Thirty-Seventh Street, New York, secretary of the committee.—The sixteenth International Red Cross Conference will be held in London in June. A special feature will be an observance of the seventy-fifth anniversary of the founding of the Red Cross movement.—The International Association of Thalassotherapy will hold its eighth international congress at Montpellier-Palavas, France, June 3-6. Subjects to be discussed are tuberculous peritonitis and meteorologic factors of the sea climate. For information apply to the organization committee, 6 rue Andre-Michel, Montpellier, France.

Government Services

Examination for Appointment in Navy Medical Corps

An examination of candidates for appointment as lieutenants (junior grade) in the Medical Corps of the U. S. Navy will be held at all naval hospitals in the United States and at the Naval Medical School, Washington, D. C., beginning May 16. Candidates must be between the ages of 21 and 32 at the time of appointment, graduates of class A medical schools and must have completed an internship of one year in a hospital accredited for interns by the American Medical Association and the American College of Surgeons. Information may be obtained from the Surgeon General, U. S. Navy, Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

New Assistants to Surgeon General

Col. Roger Brooke, medical corps, commanding officer of Letterman General Hospital, San Francisco has been appointed assistant to Dr. Charles R. Reynolds, surgeon general of the U. S. Army with the rank of brigadier general. Lieut. Col. Leigh Cole Fairbank, dental corps, General Dispensary, Washington, D. C., received a similar appointment and is the first dental officer ever to be appointed to the rank of brigadier general. As assistant to the surgeon general he will supervise the work of the army dentists.

CORRECTION

Effects of Alcohol—In the article by Sydney Selesnick in THE JOURNAL, March 12, page 775, appeared an illustration unfortunately without due acknowledgment to the original artist. Dr. Selesnick informs us that by an oversight acknowledgment of the source of original publication of the illustration was omitted. The drawing from which the illustration was adapted appeared first on page 136 of *Alcohol and Man* (New York: Macmillan Company, 1932) in chapter VI, on the human toxicology of alcohol by Emil Bogen, Ph.D.

Medical Research in England

In the annual report of the Medical Research Council for 1936-1937 the government is said to have provided an additional \$150,000 for research with special reference to chemotherapy. The success of sulfanilamide shows that chemotherapy can be useful in bacterial diseases, as it has been in protozoal and spirochetal diseases. So far the chief role of chemotherapy has been in tropical diseases of men and animals and it has depended on German science and industry almost entirely, the most notable exception being trypanosomiasis, which is of American origin. Yet several fundamental discoveries in chemotherapy have been made in England. In 1904 Thomas and Breml first demonstrated the trypanocidal action of atovyl, an organic arsenical compound. In 1907 Plimmer and Thomson discovered the trypanocidal action of antimony and potassium tartrate, and the value of this drug in bilharziasis was established by British workers. These discoveries initiated intensive research for compounds superior to the original ones, but this was carried out abroad. In Germany, where research in chemotherapy has been so successful, it has been carried out by manufacturing firms who employ hundreds of chemists and persevere for a decade or more before achieving a result susceptible of commercial development. British firms cannot do this without government support. The matter is more serious than one of prestige, for in the event of war the British Empire might find itself deprived of essential drugs. It is proposed to set up a central research laboratory with a staff giving its whole time to some laborious research and also to assign work to different academic centers. The scheme will differ from the German method in that it will not aim solely at financial success.

SULFANILAMIDE AND RELATED COMPOUNDS

The great value of sulfanilamide in puerperal sepsis was established at Queen Charlotte's Hospital, London, by Colebrooke of the council's staff and by others. The case mortality has been reduced to 5.5 per cent, against 22.7 per cent before the use of the drug. Another striking result is that after the treatment has been begun the infection has usually ceased to extend, so that there has been a great reduction in the incidence of peritonitis and a similar reduction in the development of palpable pelvic or pelvic-abdominal inflammatory masses. A similar reduction in the mortality of puerperal sepsis in London as a whole, from an average of 1.57 per thousand births to 0.75, has been observed. Benefit in other streptococcal infections has also been recorded, particularly in erysipelas and streptococcal meningitis. Animal experiments indicate that sulfanilamide also has curative effects in infections by meningococci, typhoid and other coliform bacteria, in dysentery and, somewhat less impressively, in infections by pneumococci and staphylococci. But it is too early yet to assess the value in human cases. In *B. coli* infections of the genito-urinary tract sulfanilamide bids fair to replace mandelic acid.

THE INFLUENZA VIRUS

The characteristic virus of influenza was obtained in throat washings from patients during the 1933 epidemic. A report to be published by the council points to the conclusion that in man influenza is a recognizable clinical entity, differing in symptoms and in epidemiologic character from other catarrhal infections of the respiratory tract. A means of differentiation by clinical examination alone would be an important advance. Dr Stuart

Harris showed that, whereas the onset of epidemic influenza is usually sudden, the onset of febrile catarrh is often insidious, that in influenza constitutional symptoms predominate, while in febrile catarrh respiratory symptoms are the most common, that the cough in influenza is short and dry, while in febrile catarrh it is most often paroxysmal, irritating, painful and productive. These studies have clarified the problem but they do not provide the physician with a certain method of differential diagnosis by clinical examination alone. In the 1936-1937 epidemic, 600 soldiers were vaccinated against influenza by means of an inactivated virus but the results were inconclusive. However, the vaccination was shown to be harmless and it caused the appearance in the blood of antibodies to the virus.

Vitamin B Deficiency

At the Royal Society of Tropical Medicine and Hygiene a discussion took place on vitamin B deficiency. Prof R B Hawes confined himself to acute beriberi in which the patients were desperately ill, vomiting, breathless and groaning with epigastric pain. They were often pulseless, with enlarged hearts and a pulse rate of from 120 to 130. The use of large doses of vitamin B produced a series of reactions which were unique and altered many current ideas. The vitamin must be given by injection and the effect of one injection lasted for many weeks. Clinical improvement occurred before any alteration was apparent in the blood pressure, which was usually noticed in the second hour or later. Then the diastolic pressure rose, in many cases to well above normal, and the peripheral arteries palpably stiffened. Pure vitamin B deficiency had no relation to any anemia.

Prof A R Peters stated that the first symptom of vitamin B deficiency in animals was lack of appetite, which was followed by loss of weight. When the weight had fallen to 65 per cent of the maximum possible, terminal symptoms—decreased sugar tolerance and nervous symptoms—appeared. In pigeons, optic atrophy developed. Changes in temperature also occurred and there was usually lack of vision and bradycardia. Sometimes there was edema. Cure took place rapidly when the vitamin was given. The symptoms of vitamin B deficiency were mixed up with those of general inanition, but it was now possible to separate the two.

Dr B S Platt said that there were substances normally present in human blood which bound bisulfate and were increased in fulminating beriberi. Pyruvic acid was one of these and normal levels were restored in ten or fifteen hours after intravenous administration of 5 mg of vitamin B. He called attention to accentuating factors which might be more important in the development of the various clinical types of beriberi than the grade of vitamin B deficiency. These were fever, increased intake of carbohydrates and muscular effort. They affected metabolism and led to accumulation of pyruvic acid in the blood in states of vitamin B deficiency.

British Physicians and Their Austrian Colleagues

In a joint letter to the medical press Lord Horder, Sir Arthur Hurst, Prof J A Ryle, Dr Robert Hutchison, Dr E P Poulton, Prof W H Wynn and other leaders of the profession have expressed alarm at the possible fate of their colleagues in Austria. They state that there are in that country many revered physicians and surgeons who are likely to fall into disfavor with the national socialist government either on account of their medical or social views or on account of belonging to the Jewish race. Judging from what has happened in Germany, they are afraid that serious discrimination will be exercised against these physicians. The signatories beg their colleagues in all countries to watch the progress of events with the closest attention and to do all in their power, whether by public protest or by public or private assistance to stand by any members of our profession who may suffer hardship under the new regime.

Radium Needles Recovered in Cinder Track After Eight Years

Physicians experimenting with a neon tube radium detector (named "the hen" because of the clucking sound produced) have discovered in the grounds of the Royal Victoria Infirmary, Newcastle-on-Tyne, eight milligram needles of radium which were lost eight years ago. They were left in used dressings by mistake, passed through the incinerator, and afterward became embedded with clinkers in a cinder track. A few days after the loss physicians searched the track, but with the comparatively crude instruments then available they recovered only a minute particle of radium and gave up hope of finding the rest. Recently the new instrument for detecting radium was purchased. It necessitates the use of head phones, with which the physicians have for some days been searching the track. The nearer the radium, the faster the clucking. The value of the radium recovered was \$600.

Medical Examination of All Chauffeurs

For years the medical examination of chauffeurs of motor trucks and public conveyances has been obligatory in France. The extension of this requirement to conductors of all types of motor vehicles resulted in the appointment of a committee by the Academie de medecine, the leading medical organization of France. At the February 22 meeting the committee recommended the application of obligatory medical examination to every one who drives an automobile. Prof. Henri Claude raised the question as to whether such an obligatory medical examination should include only those who had already been granted a license without such an examination or whether only present and future applicants for licenses to drive passenger automobiles should be compelled to submit to a medical examination. Of 2,678,000 automobiles in use during 1937, less than a million were motor trucks and busses. In addition there were 510,000 motorcycles in daily use. This means that, if the proposed law is to be applied to all those who possess driving permits for passenger cars and motorcycles, it would be necessary to examine over two million individuals, a huge task for physicians to undertake. There were 464,923 applicants for permits to drive all types of motor vehicles during 1937. Professor Claude stated that only a small proportion of automobile accidents are due to any defects of a pathologic character which a medical examination of drivers of passenger vehicles could prevent. From reports of the state constabulary it appears that only 0.74 per cent of accidents are the result of physical disability on the part of drivers. The majority of accidents occur because the driver suffers from some nonclassifiable mental or nervous disturbance. These individuals have a tendency to lose their self control, are often of an excitable, unstable temperament and drive at excessively high speeds. It is very difficult for any medical examiner to detect such psychic disturbances. The only solution would be to oblige such an individual following an accident for which he is responsible, to be examined as to mental and physical defects with the object of refusing a license to drive in the future. Professor Claude did not question the necessity of a medical examination to detect cardiovascular lesions, disturbances of sight or hearing, alcoholism and intercurrent diseases. Prof. Georges Guillain, neurologist, said the fact that there was such a large number of drivers of passenger automobiles ought not to serve as an obstacle to their examination. A driving license should never be granted without a medical examination. He knew more than thirty persons who suffered from a major form of epilepsy but who had been granted driving licenses in spite of the fact that the authorities had been notified of the danger. He also knew persons suffering

from paraplegia, hemiplegia and mental defects who were driving automobiles. There is absolutely no reason why a medical examination of all chauffeurs should not be obligatory in France.

Symposium on Chemotherapy in Gonorrhea

The February 11 meeting of the Societe de medecine de Paris was devoted to the discussion of the value of chemotherapy in the treatment of gonorrhea. The first paper was read by Professor Levaditi, who believes that the newer preparations do not act like ordinary antiseptics but undergo marked transformation in the body. The various drugs like sulfanilamide are of much less value in the chronic than in the acute forms of gonorrhea. When given alone, it is necessary to employ such large doses that systemic complications are likely to appear, hence these newer drugs can be regarded only as adjuvants to local methods, such as lavage. Dr. Marcel Pinard and his co-workers reported excellent results in acute cases, the percentage of cures in from three to four days being high. No other treatment was given in these acute cases. Dr. Sauphar disagreed with the preceding observations as to the efficacy of sulfanilamide and similar drugs in acute cases and said that we have still much to learn, wherefore the older methods should not be abandoned. It is unfortunate that the indiscriminate sale by druggists of these newer remedies permits many patients to try to treat a case of acute gonorrhea without proper medical supervision as to when a cure has taken place. This aspect of the question is an important one from the standpoint of spread of the infection. Dr. Lavenant stated that the best results are observed in subacute and chronic cases. However, large doses are apt to be followed by complications such as asthenia, anemia and leukopenia. Much smaller doses can be given if chemotherapy is combined with lavages. Dr. Marcel reported the cure of the majority of seventy acute cases of prolonged duration, with and without complications. He also called attention to the necessity of not allowing the indiscriminate use of these newer drugs, the doses recommended by pharmaceutical houses being usually much higher than safe or necessary. Dr. Barbellion said that a combination of local treatment and chemotherapy had given 85 per cent cures in 120 subacute and chronic cases. Systemic symptoms, in the form of a tired feeling, pallor and occasionally cyanosis, had been frequently noted. Chemotherapy should not be used indiscriminately for every case of gonorrhea. The dose of sulfanilamide and similar preparations should never exceed 3 Gm. a day. Every patient should be seen daily in order to control the action of these newer preparations adequately. The use of sulfanilamide in the various forms of tuberculosis was recommended by Dr. Marcou. It was efficacious only in cases of mixed infection, especially tuberculous diseases of the skin, bones and viscera.

Suicide Resembling a Laboratory Experiment

At the February 14 meeting of the Societe medicale des hopitaux a case was reported by Profs. A. Lemerre and P. Ameuille which is unique. A foreign physician aged 29, who came to France six years ago to study bacteriology, was seen April 23, 1932, complaining of headache and general malaise of six days' duration. The temperature during this period varied from normal to 105 F. The hemoculture, blood count and physical examination were negative. The patient stated that at the age of 21 a diagnosis of pulmonary tuberculosis had been made but no bacilli had been found. An epidermal tuberculin test, however, was positive a few months before the onset of the present illness. There was a history of tuberculosis in the family. The case was puzzling until it was ascertained that the patient had been depressed and that in the effort to commit suicide had injected 2 cc. of an emulsion of living tubercle bacilli intravenously, the day the first symptoms of his present illness appeared. The emulsion contained about 1 mg. of tubercle bacilli per cubic millimeter. With this information to work on, a blood culture by the Lowenstein technique was made for tubercle

bacilli but was negative. The same was true of two guinea pigs inoculated intraperitoneally with the patient's blood. No tubercle bacilli were found in the urine. The condition remained stationary from April 27 to May 19, the chief symptom being a feeling of fatigue. The x-ray examination of the chest May 19, thirty-two days after the inoculation, revealed multiple small shadows over both lungs, such as are seen in incipient cases of acute miliary pulmonary tuberculosis. There was an absence of any changes to be elicited on physical examination, and no tubercle bacilli were found in the scanty expectoration. Beginning about May 19 the temperature curve was of the remittent type, rising as high as 104 F toward evening. A second x-ray examination July 2 revealed far more advanced changes, characteristic of an acute miliary tuberculosis. Five days later, rigidity of the neck and a positive Kernig sign were noted. Death took place July 14, about three months after the inoculation. A necropsy was not made. Such a primary localization in the lungs and secondary localization in the meninges is frequently observed in acute miliary tuberculosis. The case is of interest because the question arises of reinfection in patients who present a positive epidermal tuberculin reaction.

Treatment of Late Effects of Poliomyelitis

The Berlin Medical Society recently discussed the treatment of the late effects of acute anterior poliomyelitis after a lecture by Dr. B. Kreuz. For about one and one-half years following the acute state one may anticipate spontaneous remission of the crippling. During this period exercise therapy should be begun to prevent atrophy of disuse in the still healthy musculature, underwater exercises are particularly beneficial. The goal of exercise therapy must be to have the patient ambulant in from six to eight weeks. If this is to be achieved, one should not hesitate to utilize reinforced partial molds for the limbs, and similar appliances. Care should be taken that the patient is subsequently freed from habituation to the appliance. Possible contractures are also removed during this one and one-half year period exercise therapy. Only at the end of this period should orthopedic surgical measures, if necessary, be introduced. Not a great deal may be expected of the latter. The muscle most utilized in plastic operations is the extensor hallucis longus. Plastic operations are undertaken after all possible deformities and contractures have been presumably corrected. For cases in which muscle plastic operations are not practicable, arthrodesis may bring about favorable results. Treatment of the upper arm by this method has occasionally been beneficial. Operations on the lower extremities should not be performed unless the surgeon feels confident that the fixation of the joint will not prevent the exercise of the patients' chosen occupation, if he has one. If his working capabilities are to be safeguarded, the crippled patient should receive careful and competent vocational guidance.

The Heritability of Metabolic Disorders

Dr. A. Boeger of the First Medical Clinic of Munich University has published a study of the heritability of metabolic disorders. A fundamental consideration in dealing with this problem is the fact that disturbances of metabolism are quite frequently based on constitutional defects. The latter in turn are the result not only of inherited anomalies but of environmental influences as well. To be sure, one set of factors or the other may remain definitely in the background in certain cases. In a vast number of persons obesity is based on excessive intake of food and insufficient exercise; occupation may also be a factor, as among cooks and hotel keepers. Endogenous obesity, on the contrary, has its etiology in an autonomous diminution of metabolism. In such cases the person lays on

excessive fat despite a dietary that normally would not increase the body weight. Therefore, only obesity of the endogenous type is heritable. Inherited modifications of certain endocrine glands or of the mesencephalon are also capable of producing the condition. Among diabetic patients the number of those who have inherited the disorder fluctuates between 15 and 25 per cent. Congenital deficiency of Langerhans' cells will always be a telling factor in the manifestation of diabetes. Possibly, exogenous factors in the etiology or liberation of diabetes are alcoholism, arteriosclerosis and overnourishment. The complete clinical picture of exophthalmic goiter is based on both a hereditary predisposition and environmental influences, among the latter fright, overwork, iodine and so on. Inherited disturbances of the sympathetic nervous system are often recognized early, whether the genetic character is dominant or recessive has not yet been determined. In cases of goiter, egregious familial diatheses marked by hyperergic conditions of various kinds are observable, a study of the relatives often reveals asthma, vasomotor rhinitis, migraine and urticaria. Besides, the importance of exogenous factors in the pathogenesis of gout are well known. Alkaptonuria and cystinuria are doubtless heritable anomalies of metabolism, but these conditions are not of any great practical significance since they usually run an asymptomatic course. It is a surprising fact that persons affected with the last named disorders often present a familial history of intermarriage.

The Heart in Cases of Pulmonary Embolism

Prof. C. Kroetz and his co-workers reported their observations before the Hamburg Medical Society, stressing the demands made on the heart and coronary vessels by pulmonary embolism and pneumothorax. Accordingly there are no signs of a functional coronary insufficiency in pulmonary embolism. The hearts of twelve patients who had died of pulmonary embolism showed no fresh ischemic necrosis of the myocardium on serial section. If infarcts and cicatrices of infarction were present, they were plainly conditioned by a thrombotic occlusion of the vessel, which antedated the pulmonary embolism. Accordingly, the concept of a pulmocoronary reflex as the cause of precordial pain and danger to the heart in cases of pulmonary embolism is deprived of any anatomic basis. Electrocardiographic variations registered following pulmonary embolism cannot be interpreted as signs of functional coronary insufficiency. These newer concepts were verified by experiments on animals. In dogs no electrocardiographic coronary signs were demonstrable in connection with repeated pulmonary embolism, only with myocardial degeneration did alterations appear in the electrocardiogram. The coronary vessels become constricted following pulmonary embolism only for an initial period of a few seconds, which period coincides with the fall of blood pressure in the systemic circulation. The coronary arteries then become dilated and remain so from five to thirty minutes. Tests following enervation of the heart and the hilus of the lung show that coronary vasodilatation following pulmonary embolism should not be ascribed to a pulmocoronary reflex but to a nutritional reflex autochthonous to the heart. Precordial pain following pulmonary embolism differs essentially from anginal pain despite a clinical similarity and it is not based on hypoxemic-coronary factors. In pneumothorax a hyperfunction or hypofunction of the right side of the heart occurs in proportion to the decreased pulmonary expansion. The nature of this phenomenon was determined in animal experimentation from the state of pressure in the pulmonary artery and the product of amplitudinal frequency in the systemic circulation. Blood perfusion of the coronary vessels exhibits the same contrasts; as a rule, hyperfunctioning of the right side of the heart corresponds to an increase in the perfusion of the right coronary artery. Here too no pulmocoronary reflexes of contraction are found; the cardiac blood perfusion is governed by nutritional demands.

The Revision of 3,000 Medical Diplomas

The ministry of health gained information about a criminal investigation by the public prosecutor A sham lawyer, Manevici, procured medical and pharmaceutical "libera practica," the right to free medical practice, in a fraudulent way In a workshop was found a heap of forged imitations of seals of several European faculties of medicine and of various magistrates, mayors and notaries The public prosecutor has investigated the diplomas of all "professional men" whose right to free practice was obtained through the mediation of Manevici and this state of affairs made it necessary to undertake the revision of all libera practica rights obtained since 1919 by those who acquired their diplomas abroad

These offenses were of formal importance, as they were apt to undermine the prestige of the medical and pharmaceutical professions The ministry of health regarded it as a duty to require strict verification and to withdraw the libera practica right to practice medicine As the ministry of health had not been provided with the necessary authority to execute these two procedures, it was necessary to provide authority for this through the legislature This was done and the ministry of health was authorized to revise and verify the libera practica and other documents with which this right was obtained, also to suspend a libera practica obtained fraudulently A committee of judges and physicians was appointed to do the work of revision

At the time of the armistice in 1918, when Rumania increased its territory by the addition of Bessarabia, Transylvania, Bucovina and the Banate, all physicians in these new territories automatically acquired the right to practice medicine, and their diplomas were recognized as valid in the whole territory of Rumania Now these diplomas are subject to revision that is, all foreign diplomas that were issued outside the prewar kingdom of Rumania and the present Rumania All diplomas have to be sent to the commission in Bucharest Doctors who acquired their diplomas prior to 1919 have to send their original diplomas, a copy of these and their citizenship papers Those who obtained their diplomas abroad after 1919 have to produce their diploma their birth certificate, citizenship papers, a certificate of morality, their matriculation certificate, the official gazette in which their libera practica was announced and a list of the subjects which they studied at the foreign university The number of diplomas to be revised amounts to more than 3,000

Uterine Cancer in Rumania

At a recent surgical congress in Paris, Prof Constantin Daniel and Dr D Mavrodin gave an account of cervical uterine cancer in Rumania The basis of the report was their own experience and the observations of thirteen surgeons and one radiologist who answered a questionnaire sent to them Their observations embraced 4,000 cases 1 Valuable data were supplied to them by the Bucharest Demographic Institute Taking the data of the Bucharest mortality rate in 1936, it can be seen that, in general, cancer is not much increased Out of 19,000,000 inhabitants of Rumania 6,121 (2,548 male and 3,573 female) died of cancer, this means a mortality rate of 32 per hundred thousand Cancer of the cervix uteri caused death in 1,648 cases in 1934 and in 1,733 cases in 1936 corresponding to a general cancer mortality of 14.2 per cent in the 4,000 cases embraced in Daniel and Mavrodin's report In relation to genital cancer cervical cancer occupies first place At the gynecologic clinic of the Coltea hospital in Bucharest 85 per cent of the genital cancers were cervical cancers According to the data of the Bucharest Demographic Institute of 1888 fatal genital cancers 1,733, or 90.32 per cent were uterine

cancers The cervical cancers of the Bucharest gynecologic clinic were associated with uterine fibroma in 7.97 per cent of the cases In Rumania, cervical cancer was most frequent in multiparas, according to the Bucharest Third Surgical Clinic the rate was 70 per cent In the majority of cases the lesions were so severe that the patients were declared incurable According to the Geneva classification among the cases at the Bucharest obstetric and gynecologic clinic 10.99 per cent were of the first degree, 27.14 per cent second degree and 51.54 per cent third and fourth degree Cases at the provincial hospitals afforded a worse picture The period between the first manifestation of the disease and the time the patient called on a doctor was generally between two and three years In Rumania practitioners generally make no diagnosis without the microscope The most frequent form at the Rumanian clinics is the vegetative form, which occurs in 49.33 per cent, ulcerative forms were found in 18 per cent infiltrated forms in 6 per cent and endocervical hypertrophic in 25.33 per cent The first place in treatment is occupied in Rumania by surgery Radioactive procedures, owing to the shortage of radium, are not generally accessible According to Rumanian surgeons, radical surgical treatment is indicated in all first and second degree cases of cervical cancer They almost without exception remove the tumor by the abdominal route According to the questionnaire sent out by Daniel and Mavrodin the majority of our surgeons prefer to do the Wertheim total hysterectomy The operative mortality varied between 4.83 and 8.82 per cent Though seldom done in Rumania the removal of the tumor through the vagina gave good immediate results Radium is reserved for third and fourth degree cases, for patients whose conditions contraindicate surgical intervention and in cases of recurrence In private practice no radium treatment is given yet in Rumania

CAMPAIGN AGAINST CERVICAL CANCER

In Rumania as yet there is no definite anticancer campaign in operation, although many efforts have been made in the interest of diminishing its ravages Public lectures are being given on the early recognition of cancer and graduate courses are arranged for doctors, lectures are given to doctors on the importance of periodic examination of bleeding patients, on the necessity of biopsy, on the surgical treatment of localized cervical cancer and on the advantages of irradiations in inoperable cancer Every year a special "cancer week" is arranged The Societatea Anatomica Pentru Studiul Cancerului brought out a film with the title "Cancerul," which was shown in connection with the lectures Articles appear in the lay journals from time to time pointing out the dangers of cancer As regards a scientific campaign against cancer, an organization was formed under the leadership of Professor Daniel in 1929 Another recently established organization is the Societatea Romana de Cancerologie

Marriages

HERBERT DE GRAVE WOLFF JR Alexandria Va, to Miss Anne Henderson Froehling of Richmond, February 12

CHARLES R WILLIAMS, Birmingham Ala, to Miss Alice Virginia Futral in Wadley, Ga, in February

WILLIAM T WARD, Raleigh, N C to Mrs Mary Powell Ward of Franklinton in December 1937

HOWARD L VAN WINKLE to Miss Wilma Willimack, both of Cedar Rapids Iowa, March 3

RICHARD B RAY to Miss Carolyn Haldene Fuller, both of Durham N C, February 12

JAY E HOLLAHAN, Mason City, Iowa, to Miss Beulah Sanders of Creston March 1

JESSE B WILDEMBERG to Miss Jean Miller, both of New York, February 12

LEON RAYO, Spinal, Colo, to Miss Lillian Karsh, Oct 3, 1937

Deaths

Courtland Yardley White * Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1895, associate professor of bacteriology at the Medical Chirurgical College, Graduate School of Medicine, University of Pennsylvania, member of the American Association of Pathologists and Bacteriologists and the American Society of Clinical Pathologists, instructor in clinical medicine at his alma mater, 1899-1904, lecturer and demonstrator in morbid anatomy, veterinary department, University of Pennsylvania, 1899-1910, director of the pathologic laboratories of the Episcopal Hospital, 1908-1938, director, City of Philadelphia laboratory of bacteriology, 1910-1938, formerly on the staffs of the Children's, St. Joseph's and Jewish hospitals, aged 64, died suddenly, January 14, of coronary sclerosis

Henry Lindsay Sanford * Cleveland, Harvard University Medical School, Boston, 1900, assistant clinical professor of genito-urinary surgery, Western Reserve University School of Medicine, secretary and past president of the American Association of Genito-Urinary Surgeons, member and past president of the American Urological Association, fellow of the American College of Surgeons, past president of the Cleveland Academy of Medicine, in 1914 member of the city board of health, served during the World War, on the staffs of the Lakeside Hospital, Cleveland City Hospital and St. Alexis Hospital, aged 64, died, February 5, in the University Hospital of coronary occlusion and bronchopneumonia

James Alfred Spalding, Portland, Maine, Harvard University Medical School, Boston, 1870, member and past president of the Maine Medical Association, past president of the Cumberland County Medical Society, member of the American Academy of Ophthalmology and Oto-Laryngology and the American Ophthalmological Society, fellow of the American College of Surgeons, on the staff of the Maine General Hospital, editor of the *Maine Medical Journal*, from May 1933 to September 1935, author of "Life of Dr. Lyman Spalding" and "Maine Physicians of 1820", aged 91, died, February 27

Frederick Warren Smith * Philadelphia, Hahnemann Medical College and Hospital, Philadelphia, 1903, clinical professor of laryngology and rhinology at his alma mater, fellow of the American College of Surgeons, served during the World War, on the staffs of the J. Lewis Crozer Home for Incurables and Homeopathic Hospital, Chester, West Chester (Pa.) Homeopathic Hospital, Wilmington (Del.) Homeopathic Hospital and the Abington (Pa.) Memorial Hospital, aged 56, died, February 20, in the Hahnemann Hospital

Francis Cruger Edgerton * New York, Columbia University College of Physicians and Surgeons, New York, 1898, fellow of the American College of Surgeons, member of the American Association of Genito-Urinary Surgeons, formerly clinical instructor in surgery, department of urology, Cornell University Medical College, New York, on the staffs of St. Elizabeth's and St. Francis, New York and St. Mary's Hospital, Hoboken, N. J., aged 64, died, February 19, in the Doctors Hospital, of pneumonia

Paul Eugene Bowers, Los Angeles State College of Physicians and Surgeons, Indianapolis, 1907, member of the California Medical Association and the American Psychiatric Association, served during the World War, at one time superintendent of the Indiana Hospital for Insane Criminals, Michigan City, author of "Clinical Studies in the Relationship of Insanity to Crime" and "Manual of Psychiatry for the Medical Student and General Practitioner", aged 51, died, February 15, of cardiorenal disease

Charles Gluck, New York, Long Island College Hospital, Brooklyn, 1908, served during the World War, at various times on the staffs of the Mount Sinai Hospital, Sydenham Hospital, St. Luke's Hospital and Harlem Eye and Ear Hospital, New York, owner of the Passaic (N. J.) Eye, Ear, Nose and Throat Private Hospital, aged 52, died, February 15, in the Flower-Fifth Avenue Hospital, of septicemia, as the result of pricking his finger while operating

Frank Bacon Hancock, Philadelphia University of Pennsylvania Department of Medicine, Philadelphia, 1897, member of the Medical Society of the State of Pennsylvania, veteran of the Spanish-American War, for many years police and fire surgeon, aged 65, died, January 18, of pulmonary tuberculosis and arthritis deformans

David Aaron Goodman, Old Forge, Pa., Jefferson Medical College of Philadelphia, 1915, member of the Medical Society

of the State of Pennsylvania, president of the school board formerly deputy coroner, served during the World War, on the staff of the Taylor (Pa.) Hospital, aged 46, died, January 5, of coronary occlusion

Alexander Berkley Raff, Chicago, Jefferson Medical College of Philadelphia, 1905, for many years member of the board of health, at one time acting medical director of the Sanatorium of the Jewish Consumptives' Relief Society, Spaulding, Colo., aged 56, died, February 11, in the Michael Reese Hospital, of pneumonia

Harry Burton Fuller * Chicago, Rush Medical College, Chicago, 1913, member of the American Academy of Ophthalmology and Oto-Laryngology, fellow of the American College of Surgeons, aged 51, on the staff of the Chicago Eye, Ear, Nose and Throat Hospital, where he died, February 4, of coronary thrombosis

George Wallace Willcox, Hamilton, N. Y., New York Homeopathic Medical College and Hospital, New York, 1899, member of the Medical Society of the State of New York, served during the World War, aged 71, died, January 27, in the Utica (N. Y.) Memorial Hospital, of coronary thrombosis

Raymond Brooke Essick, Murphysboro, Ill., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908, member of the Illinois State Medical Society, aged 52, on the staff of St. Andrew's Hospital, where he died, February 16, of cerebral hemorrhage

Andrew Joseph Ware, Greenville, Miss., Memphis (Tenn.) Hospital Medical College, 1903, formerly city and county health officer, at one time superintendent of the Matty Hersee Hospital, Meridian, aged 54, died, January 30, in a hospital at Jackson, of chronic nephritis and hypertension

Arthur Parsons, Geneseo, Ill., College of Physicians and Surgeons, Keokuk, Iowa, 1892, member of the Illinois State Medical Society, served during the World War, formerly mayor and member and president of the high school board of education, aged 69, died, January 9

Ellerslie Wallace Richards * Easton, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1899, served during the World War, for many years school physician, on the staff of the Easton Hospital, aged 65, died, January 6, of carcinoma of the sigmoid

John Houston Ball, Abilene, Texas, Memphis (Tenn.) Hospital Medical College, 1892, past president and secretary of the Stephens County Medical Society, for several years county health officer, aged 70, died, January 19, in the Hendrick Memorial Hospital, of heart disease

Adolph Bernard Quasser, Jacksonville, Fla., Harvard University Medical School, Boston, 1922, member of the Florida Medical Association formerly on the staffs of the Mercy and Portsmouth General Hospital, Portsmouth, Ohio, aged 41, died, February 3, of brain tumor

Charles Roland * Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1898, member of the Associated Anesthetists of the United States and Canada, formerly health officer of Reading, aged 62, died, January 17, of carcinoma of the tongue

Henry E. Beebe, Sidney, Ohio, Homeopathic Hospital College, Cleveland, 1873, for many years a member and at one time president of the state medical board, fellow of the American College of Surgeons, aged 88, died, February 12, of cardiovascular disease

Albert J. Pounds, Delaware, Ohio, Columbus Medical College, 1881, formerly city health commissioner, member of the county board of health, president of the board of education and county coroner, aged 79, died, January 12, of carcinoma of the stomach and intestine

Francis Edward Heid * Brockway, Pa., University of Maryland School of Medicine, Baltimore, 1913, past president of the Jefferson County Medical Society, on the staff of the Maple Avenue Hospital, DuBois, aged 49, died, January 27, of heart disease

Charles Lyon Fullmer, Renovo, Pa., Jefferson Medical College of Philadelphia, 1883, member of the Medical Society of the State of Pennsylvania, at one time county coroner for many years school physician, aged 78, died, January 29, of myocarditis

Henri Romeo Vallee, Montreal, Quebec, Canada, School of Medicine and Surgery of Montreal, 1918, aged 42, on the staffs of the Lachine General Hospital, St. Joseph Lachine and the Hospital Ste. Jeanne D'Arc, where he died, January 13

William Stewart Russell * Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1903, on the staff of the Pennsylvania Hospital, aged 62, died, January 20, in the Philadelphia General Hospital, of meningo-encephalitis

John H Sampson, St Joseph, Mo, Missouri Medical College, St Louis, 1881, member of the Missouri State Medical Association, at one time professor of pediatrics at the Emsworth Medical College, aged 81, died, February 10, of pneumonia

Karle Henry Granger, Weymouth Mass, Dartmouth Medical School, Hanover, N H, 1893, member of the Massachusetts Medical Society, school physician, aged 69, died, Dec 28, 1937, in the Baker Memorial Hospital, Boston

Edmund Henry Lewis, Gordonsville, Va, Jefferson Medical College of Philadelphia, 1887 member of the Medical Society of Virginia, aged 76, died, February 4, in the University Hospital, Charlottesville, of pneumonia

William Willis Wray, Louisa, Ky, Baltimore Medical College, 1897, member of the Kentucky State Medical Association, aged 67, died, January 12 in the General Hospital of uremia and carcinoma of the bladder

Thomas C Rummel, Tacoma Wash, Western Reserve University Medical Department, Cleveland, 1891, member of the Washington State Medical Association, aged 78, died, February 14, of cerebral hemorrhage

William Peyton Beane, Keystone, W Va, University of Tennessee College of Medicine, Memphis, 1912, member of the West Virginia State Medical Association, aged 59, died, February 16, of cerebral hemorrhage

Lyndon S Smith Ⓢ Monongah, W Va, Baltimore Medical College, 1901, physician for the Consolidated Coal Company at Monongah, aged 65 died, January 31, in the Cook Hospital, Fairmont, of cerebral hemorrhage

Grant J A New, Pittsburgh, Western Pennsylvania Medical College, Pittsburgh, 1895, member of the Medical Society of the State of Pennsylvania, aged 68, died, January 11, of myocarditis and chronic nephritis

Elbert Eells Dewey, Chicago, Chicago Medical School, 1921, member of the Illinois State Medical Society, on the staff of the West Side Hospital, aged 60, died, February 2, in Lake Bluff, Ill, of heart disease

Leigh Harrison Hunt, New York, University of the City of New York Medical Department New York, 1880, noted etcher, art lecturer and critic, aged 79, died, Dec 16, 1937, in the Mount Sinai Hospital

Charles Pottberg, Philadelphia, Jefferson Medical College of Philadelphia, 1883, member of the Medical Society of the State of Pennsylvania, aged 81, died, January 9, of chronic myocarditis and endocarditis

Alice Maude Smith, Tacoma, Wash, Northwestern University Woman's Medical School, Chicago, 1896 member of the Washington State Medical Association, aged 71, died, January 11, of epigastric hernia

Joshuaway Ilar Glover, Union City, Tenn, Kentucky University Medical Department, Louisville, 1906, member of the Tennessee State Medical Association, aged 57, died, February 14, of chronic nephritis

John Preston Carver, Simsbury, Conn, Albany (N Y) Medical College, 1896, member of the Connecticut State Medical Society, aged 66, died, February 4, of acute toxic myocarditis with complications

Warren Rice Flanagan, Continental, Ohio, Ohio State University College of Medicine, Columbus, 1935 member of the Ohio State Medical Association, aged 34, died, February 11, in an automobile accident

Owen Joseph McGovern Ⓢ Reading Pa, University of Pennsylvania School of Medicine, Philadelphia, 1917, aged 49, on the staff of St Joseph's Hospital, where he died, January 24, of rheumatic heart disease

John Frank Artelle, Wallingford, Conn, Long Island College Hospital, Brooklyn, 1878, member of the Connecticut State Medical Society, aged 83, died, February 8, of arteriosclerosis and hypostatic pneumonia

Edwin S Huntsman, Hulmeville, Pa, Jefferson Medical College of Philadelphia 1886, member of the Medical Society of the State of Pennsylvania, aged 75, died, January 5, of carcinoma of the prostate

Robert Lewis Wilson, Jeannette, Pa, Medico Chirurgical College of Philadelphia 1904, formerly on the staff of the Westmoreland Hospital, Greensburg, aged 59, died, January 21, of coronary occlusion

Brent Charles Tarbell, Naco Ariz., Kansas City (Mo) Medical College, 1901 acting assistant surgeon U S Public Health Service, aged 60 died, January 27, in the Copper Queen Hospital Bisbee

William Thomas Arnold, Hemphill, Texas, Dallas Medical College, 1904, member of the State Medical Association of Texas, member of the board of education, aged 57, died, Dec 23, 1937, of tularemia

John Lawrence Montgomery Ⓢ Los Angeles, Bennett Medical College, Chicago, 1911 aged 47, died, January 24, in the Los Angeles General Hospital, of traumatic rupture of an esophageal varicosity

Robert O'Neal Boyd, Clover, S C, Medical College of the State of South Carolina, Charleston, 1931, aged 32, died, February 3, at a sanatorium in Charlotte, N C, of pneumonia following influenza

John Waring Lewis, Keo, Ark, Tulane University of Louisiana Medical Department, New Orleans, 1904, aged 58, died, February 9, in a hospital at Little Rock, of pneumonia following influenza

Daniel Sartar Johnson Jr, Braxton, Miss, Memphis (Tenn) Hospital Medical College, 1912, served during the World War, formerly county health officer, aged 60, died in December 1937

William Bruce Payton, Riverside, Calif, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1881, aged 81, died, January 7, of coronary thrombosis and arteriosclerosis

Higgerson Matherson Sale, Washington Ga, University of Georgia Medical Department, Augusta, 1900, member of the Medical Association of Georgia, aged 67, died, February 1, of pyelonephritis

George Martin Guthrie, Inverness, Ala, Medical College of Alabama, Mobile, 1900, member of the Medical Association of the State of Alabama, aged 62, died, January 9, of influenza and pneumonia

Newman W Nanney, Fulton, Miss, Memphis (Tenn) Hospital Medical College, 1904, member of the Mississippi State Medical Association, county health officer, aged 57, died, Dec 7, 1937

James Edwin Stuart, Livingston, Mont, Willamette University Medical Department, Salem, 1909, member of the Medical Association of Montana, aged 72, died, January 4, of myocarditis

Walter Frederic Pine Ⓢ Dodge City, Kan, University Medical College of Kansas City, Mo, 1908, formerly on the staff of St Anthony Hospital, aged 67, died, January 24, of appendicitis

Thompson Anderson, Denver, University of Nashville (Tenn) Medical Department, 1901, member of the Colorado State Medical Society, aged 60, died, February 9, of lobar pneumonia

John R Wright, Louisville, Ky, University of the South Medical Department, Sewanee, Tenn, 1901, veteran of the Spanish-American War, aged 68, died, Dec 19, 1937, in Fairhope, Ala

Enoch N Gentry, Sturgeon, Mo, University of Louisville (Ky) Medical Department, 1879, member of the Missouri State Medical Association, aged 83, died, February 13, of arteriosclerosis

Henry James Goubeaud, Brooklyn, Long Island College Hospital, Brooklyn, 1890, member of the Medical Society of the State of New York, aged 68, died, February 1, of pneumonia

Thomas James Lawson, Ainsworth, Neb, Medical Department of Omaha University, 1896, aged 75, died, January 26, of acute cholecystitis, thrombophlebitis and postoperative parotitis

John Elmer Wilson, Butler Ky, National Normal University College of Medicine, Lebanon Ohio, 1896, Cincinnati College of Medicine and Surgery, 1897, aged 72, died, Dec 28, 1937

Ralph M Rusco, Chicago, Hahnemann Medical College and Hospital Chicago, 1901, aged 58, died, February 3, in St Bernard's Hospital, of intestinal obstruction and myocarditis

Wilbur W Warner, Bogalusa, La, Kentucky School of Medicine, Louisville 1894, member of the Louisiana State Medical Society, aged 68 died January 28 of coronary thrombosis

John Hughes Rothwell Ⓢ Liberty Mo, Bellevue Hospital Medical College, New York, 1883, aged 79, died, January 6, of cerebral embolism, carcinoma of the liver and arteriosclerosis

Oscar Vananda Guthrie, County Line Okla, College of Physicians and Surgeons, Little Rock, 1910, aged 51, was killed February 7, near Cross Roads in an automobile accident

Frank Joseph Sexton, Brookline, Mass, University of Pennsylvania Department of Medicine Philadelphia, 1898 aged 65, died January 4, of cerebral embolus and arteriosclerosis

Charles Mathew Gower, Trenton, Ky., University of Tennessee Medical Department, Nashville, 1895, veteran of the Spanish-American and World wars, aged 67, died, January 2

Vanderhoef Morgan Disbrow, Lakewood, N. J., University of Vermont College of Medicine, Burlington, 1880, aged 80, died, January 6, of myocarditis and arteriosclerosis

Belle C. Buchanan Burgess, Chicago, Pulte Medical College, Cincinnati, 1883, Woman's Medical College of Cincinnati, 1894, aged 84, died, January 30, of cerebral hemorrhage

Leonidas Erskine Rupert, Florence, Colo., University of Louisville (Ky.) Medical Department, 1893, aged 66, died, February 16, in Denver of myocarditis and tuberculosis

Zachary Taylor, West Jefferson, Ohio, Starling Medical College, Columbus, 1873, also a druggist, aged 88, died, January 17, of lobar pneumonia and cerebral hemorrhage

Lawrence M. Hensel, Richmond, Calif., Northwestern Medical College, St. Joseph, Mo., 1885, aged 85, died, January 30, in a hospital at Oakland, of bronchopneumonia

Samuel E. Bamford, Clio, Iowa, College of Physicians and Surgeons, Keokuk, 1889, aged 78, died, January 15, in St. Joseph's Mercy Hospital, Centerville, of pneumonia

Thomas O. Helm, Bowling Green, Ky., University of Louisville Medical Department, 1885, aged 78, died, Dec. 17, 1937, in the Norton Memorial Hospital, Louisville

George Otto Henry Buchner, Bakersfield, Calif., Cooper Medical College, San Francisco, 1907, member of the California Medical Association, aged 57, died, Dec. 12, 1937

James Francis Edward Colgan, Philadelphia, Jefferson Medical College of Philadelphia, 1892, aged 74, died, January 8, in St. Mary's Hospital, of cerebral hemorrhage

Matilda J. Gallagher, Washington, D. C., National University Medical Department, Washington, 1892, aged 75, died, February 8, of myocarditis and chronic nephritis

Halbert Joel Burdick, Cleveland Heights, Ohio, University of the City of New York Medical Department, New York, 1888, aged 73, died, January 15, of pneumonia

W. W. Kerr, Volga, W. Va., Medical College of Ohio, Cincinnati, 1892, member of the West Virginia State Medical Association, aged 72, died in December, 1937

William Thomas Buck, Beech Bluff, Tenn., Vanderbilt University School of Medicine, Nashville, 1901, served during the World War, aged 64, died, Dec. 14, 1937

Alexander C. Rinkenberger, Benton Harbor, Mich., Chicago Homeopathic Medical College, 1888, aged 68, died suddenly, Nov. 8, 1937, in the Mercy Hospital

Robert Samuel Lindsay, Old Forge, N. Y., Albany Medical College, 1890, formerly local health officer, aged 76, died, January 26, of diabetes mellitus and nephritis

Stafford Rambo, Bluffton, Ga., University of Maryland School of Medicine, Baltimore, 1891, also a dentist, aged 71, died, Dec. 25, 1937, of coronary thrombosis

Duncan Donald Campbell, Stamford, N. Y., Victoria University Medical Department, Coburg, Ont., Canada, 1884, aged 73, died January 13, of coronary occlusion

Charles Austin French, Boston, College of Physicians and Surgeons, Boston, 1893, aged 75, died, January 17, of cerebral hemorrhage and chronic myocarditis

Edward M. Parker, Emporia, Va., Maryland Medical College, Baltimore, 1900, member of the Medical Society of Virginia, aged 79, died, Dec. 16, 1937

Margaret Kennedy Sullivan, Haddonfield, N. J., Woman's Medical College of Pennsylvania, Philadelphia, 1895, aged 68, died, in January, of pneumonia

Alexander Berry Childs, Eunice, La., Tulane University of Louisiana Medical Department, New Orleans, 1907, aged 57, died in January of pneumonia

Charles Cheyne Aitken, Des Moines, Iowa, Halifax Medical College, Dalhousie, N. S., Canada, 1881, aged 81, died, January 8, of aortic aneurysm

Charles Sumner Fremont Whitcomb, Contoocook, N. H., Medical School of Maine, Portland, 1895, aged 72, died, January 2, of cerebral hemorrhage

George W. Wiley, Norman, Okla., Fort Worth School of Medicine, Medical Department of Fort Worth University, 1900, aged 63, died, Dec. 31, 1937

John Carlos Da Silva Pitta, New Bedford, Mass., Universidade de Lisboa Faculdade de Medicina, Portugal, 1884, aged 77, died Dec. 10, 1937

Edwin Harrison Moore, Pittsburgh Eclectic Medical Institute, Cincinnati, 1896, aged 76, died, January 31, of influenza and bronchopneumonia

Elmer Stanley Goudy, Vineland, N. J., Medico-Chirurgical College of Philadelphia, 1898, aged 70, died, January 24, of a self-inflicted bullet wound

Cornelius L. Bartholomew, Allentown, Pa., Jefferson Medical College of Philadelphia, 1878, aged 93, died, January 26, of coronary thrombosis

Mervin Edward Kallman, Sioux City, Iowa, Creighton University School of Medicine, Omaha, 1929, aged 30, died, January 26, of pneumonia

Jeremiah Ballard, Los Angeles, State University of Iowa College of Medicine, Iowa City, 1875, aged 92, died, January 15, of chronic myocarditis

John B. Winn, Hamilton, Texas, University of Louisville (Ky.) Medical Department, 1889, aged 82, died, January 22, of mitral regurgitation

Robert Patrick McLaughlin, Ottawa, Ont., Canada, University of Toronto Faculty of Medicine, Toronto, 1903, aged 30, died, Dec. 31, 1937

Edouard Rose, Montreal, Que., Canada, University of Bishop College Faculty of Medicine, Montreal, 1874, aged 63, died, Dec. 11, 1937

Harry Elgin Webster, Dixon, Ill., Rush Medical College, Chicago, 1910, aged 62, died, January 29, in Hillsboro, N. D., of angina pectoris

Francis Ruthven Olney, Detroit, Loyola University School of Medicine, Chicago, 1928, aged 36, died, Dec. 11, 1936, in Little Rock, Ark.

C. H. Bynum, Kinston, N. C., Leonard Medical School, Raleigh, 1896, aged 65, died, January 9, of cerebral hemorrhage and nephritis

Allison Burdette Toaz, Detroit, Detroit College of Medicine and Surgery, 1914, aged 51, died, January 31, in an automobile accident

George Warren Gleason, Cedar Rapids, Iowa, Chicago Homeopathic Medical College, 1888, aged 86, died, January 22, of myocarditis

Matilda Hunt, San Francisco, University of London Faculty of Medicine, London, Ont., Canada, 1909, aged 55, died, Nov. 28, 1937

Martin M. Christianson, Watertown, S. D., University Medical College of Kansas City (Mo.), 1898, aged 79, died, Nov. 26, 1937

William H. Nunn, Morganfield, Ky., University of Tennessee Medical Department, Nashville, 1881, aged 83, died, Dec. 18, 1937

Charles S. Russell, Hamilton, Ont., Canada, Queen's University Faculty of Medicine, Kingston, 1912, aged 49, died, Dec. 10, 1937

Albert Carl Jongewaard, Sioux Center, Iowa, Rush Medical College, Chicago, 1904, aged 57, died, January 2, of pernicious anemia

William Spencer Craghead, Denver, Barnes Medical College, St. Louis, 1895, aged 74, died, January 6, of cerebrospinal meningitis

Edgar Poe Blair, Nashville, Tenn., Vanderbilt University School of Medicine, Nashville, 1890, aged 70, died, Dec. 12, 1937

Charles James Wagner, Toronto, Ont., Canada, University of Toronto Faculty of Medicine, 1899, aged 61, died, Nov. 16, 1937

John W. Nuzum, Wick, Iowa (licensed in Iowa in 1885), aged 89, died, January 15, in Des Moines, of cerebral hemorrhage

Joseph Alexander Reeves, Whitesburg, Ga., Atlanta College of Physicians and Surgeons, 1903, aged 73, died, Dec. 15, 1937

Lindsey Gee Poe, Newark, Ark., University of Nashville (Tenn.) Medical Department, 1893, aged 68, died, January 19

Charles E. Werdman, Marcellus, N. Y., Albany Medical College, 1880, aged 82, died, January 17, of lobar pneumonia

Albert Edward Taplin, Veblen, S. D. (licensed in South Dakota in 1904), aged 71, died, January 15, of myocarditis

Charles B. McLaughlin, Fordyce, Ark. (licensed in Arkansas in 1903), aged 75, died, January 28, of myocarditis

Joseph Schulte, Detroit, Detroit Medical College, 1875, aged 88, died, January 9, of cerebral hemorrhage

F. C. Roark, Kodak, Ky., Louisville Medical College, 1901, aged 84, died in December 1937

M. H. Davis, Leapwood, Tenn., Memphis Hospital Medical College, 1895, died, January 21

Bureau of Investigation

A HAIR-RAISING FRAUD

Paul Downing, Alleged Hair and Scalp Specialist, Debarred from the Mails

The "will to believe" is the greatest asset of the "patent medicine" faker. It breaks down sales resistance, it causes fat women to accept as scientific truth the veriest balderdash about alleged short cuts to the svelt figure, it explains why hard-headed—but bald-domed—business men fall easy prey to the grow-hair-quick quacks. Men are sensitive about the loss of their hair. The trait is no modern development, it is at least as old as the time of the prophets.

While there are fashions in quackery there are also good old staple frauds that can always be counted on to deplete the sucker. Cures for baldness rank high among the staples—and Mr. Downing's cure was one of them. Paul Downing of Portland, Ore., sold through the mails a product that, if one believed Downing, would raise hair on a billiard ball. The advertising of this marvel was banally unoriginal but one doesn't have to be a creative spirit to sell cures to the bald-headed contingent.

In due time that overworked branch of the Post Office Department that investigates fraudulent mail-order schemes got around to Mr. Downing and called on him to show cause why his business should not be debarred from the mails. Downing's snappy come-back was an affidavit to Washington submitted by his attorney in which he declared that he had, a few months previously, sold his business lock, stock and barrel to one "Kenneth Ames." About the same time the Post Office officials received a letter from another Portland attorney transmitting what was described as "revised literature" said to have been recently adopted by a certain W. E. Ames. Nothing was furnished to show whether "Kenneth Ames" and "W. E. Ames" were the same person.

According to the government report the Downing "cure" came in four very small bottles, thus:

BOTTLE I—Stimulating Oil. Contained two teaspoonfuls of oil with red pepper and cloves.

BOTTLE II—Scalp Food. Contained four teaspoonfuls of a mixture of two parts oil and one part kerosene.

BOTTLE III—Restorative Oil. Contained a mixture of equal parts of oil and kerosene.

BOTTLE IV—Medicated Scalp Cleaner. Contained three tablespoonfuls of liquid soap with carbolic acid.

These four bottles and their contents cost Mr. Downing 65 cents; he sold them for \$5—which would seem to take care of considerable overhead. The instructions were simple. Use the red pepper mixture on Mondays, the weaker kerosene mixture on Wednesdays, the stronger kerosene mixture on Fridays and shampoo with the carbolic acid liquid soap once every two weeks. The five dollar "treatment" was good for five applications, then one sent for another five dollars worth.

Part of the Downing ballyhoo were before-and-after pictures of one L. F. Rose of Portland, Ore. Mr. Rose, before using Downing's red pepper, kerosene carbolic acid wonder, was shown with a head as devoid of hair as a marble statue. But after the treatment he is shown with enough hair to permit a marcel wave. The only fault one could find with these pictures of Mr. Rose is that he apparently was just as free of any eyebrows after the treatment as he was before. Nevertheless, Mr. Rose makes affidavit to the fact that "I can hardly find words descriptive enough to express my feelings and thankfulness."

The Solicitor for the Post Office Department—Judge Karl A. Crowley—after considering all the evidence in the case declared that the so-called treatment sold by Downing would not remove the cause of or cure baldness, would not produce a strong healthy, luxuriant growth of hair on the heads of persons who are bald, was not miraculous, positive or reliable in its effects and that Downing's scheme was one for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises. The Solicitor recommended that a fraud order be issued. On July 31, 1937, the mails were closed to Paul Downing.

ARTHOX OR SULFIODOXYGENIA

A "Patent Medicine" Becomes an 'Ethical Specialty'

About three years ago—in February 1935—a physician wrote to Standard Laboratories, Inc., 30 Huntington Avenue, Boston, asking that concern for the formula of its product "Arthox" which a patient had received. An advertising circular described Arthox as "a scientific medicinal formula" and as an "analgesic specially prepared to aid in the relief of the muscular aches and pains of rheumatism and arthritis." The circular gave no information regarding the composition of the product, in fact the circular was rather obviously *not* addressed to physicians.

In reply to the physician's inquiry Standard Laboratories, Inc., wrote admitting that Arthox was "an over-the-counter preparation"—that is, a "patent medicine"—and stated that the product contained "the following ingredients":

| | |
|-------------------|--------------------------|
| Alcohol (2%) | Burnham's Soluble Iodine |
| Anise | Sassafras |
| Glycerhiza | Sarsaparilla |
| Methyl Salicylate | Sodium Salicylate |

No quantities were given—except alcohol, the proportion of which the federal law requires to be declared—so the information meant little. Yet the concern claimed, in the same letter, that Arthox was being prescribed by a large number of physicians, some of them specialists in the treatment of arthritis here in the east.

This was in February 1935. A year later physicians received "literature" on Arthox stating that the preparation was sold "on physician's prescription only." As the name "Arthox" was apparently too low-brow for an "ethical specialty," that name had added to it a high-hat, and quite meaningless, synonym "Sulfiodoxygenia." Because of the number of inquiries from physicians regarding the product the Council on Pharmacy and Chemistry asked the A. M. A. Chemical Laboratory to analyze this "patent medicine." The condensed Laboratory report, with the technical details of the analytic work omitted, reads as follows:

"One original bottle of Arthox (Standard Laboratories, Inc., Boston) was submitted to the A. M. A. Laboratory for examination at the request of the Council on Pharmacy and Chemistry.

"The label on the bottle indicated that the preparation was for the treatment of arthritis and rheumatoid conditions and gave as a synonym to Arthox the term Sulfiodoxygenia."

"The bottle contained 124 ounces of a yellowish brown liquid containing a brownish sediment. Qualitative determinations indicated sodium, magnesium, calcium, iodide, sulfate, a trace of iodine and a substance yielding an odor similar to anise. Salicylates and other antipyretics and alkaloids were not found."

"The preparation was strongly acid, 1 cc. being equivalent to approximately 4 cc. of one tenth normal sodium hydroxide."

On the basis of their analyses the chemists reported that it might be concluded that "Arthox contains as its essential ingredients sulfuric acid, sodium iodide, flavoring substances and probably colchicin."

It would thus appear that the composition of Arthox has changed. The salicylates have gone; it is possible that colchicin has taken their place. It has often been said in these pages that when one buys a "patent medicine" one buys a *name* and not a *thing*. There is nothing fixed about the formula of a proprietary medicine, the maker can change it overnight if he so desires or if commercial expediency so dictates. Many a "patent medicine" on the market today bears but little resemblance to its original namesake. The manufacturers of Arthox have at least a good precedent for such changes in formula as they have seen fit to make.

1. A substance insoluble in petroleum and capable of extraction from acid aqueous solution with chloroform was found. The substance was suggestive of colchicin but the amount was small and the identity reactions were never clear-cut.

Correspondence

TESTS FOR ALCOHOLIC INTOXICATION

To the Editor—I read with interest and admiration the article in *THE JOURNAL*, March 12, by Selesnick concerning alcoholic intoxication and also the article in the same issue by Harger, Lamb and Hulpieu, describing a test for intoxication employing breath. Both articles are scholarly, well prepared and absolutely sound from a scientific standpoint, but, from the point of view of the rural general practitioner an attitude must be taken, less strictly accurate, perhaps, from the laboratory expert's angle, but none the less effective and efficient for the practical purposes of everyday life.

In the first place, both articles, in my opinion, paid less attention than they should have done to the fact of the personal equation—of variations in individual susceptibility. No one would deny that a dose of alcohol that might well kill an infant would have a far less deleterious effect on a seasoned drinker, and any practical physician knows that a given degree of intoxication (including the blood, urine, spinal fluid, and what-not concentrations) produces less clinical manifestation in some individuals than in others with a higher tolerance. A concentration of alcohol that would render one individual definitely incapable of operating a motor vehicle might not produce such an effect in another.

Secondly, one wonders whether such ultrascientific and comparatively complicated tests are actually called for in determining whether or not a given individual is drunk. It is my thought that most general practitioners who are accustomed to exercise common sense in their professional life would be able, after a moderately thorough physical examination and a fairly brief observation of the individual, to say whether or not, in their opinion, he was drunk enough to render him incapable of driving a car. One wonders too whether the results of the careful investigations of the laboratory scientist are of any more real value in a court of law than the sworn professional opinion of one or more experienced and practical doctors.

Far be it from me to decry the investigations of the trained laboratory worker, which are indispensable to modern practice, my reaction merely was, after reading the excellent articles referred to, to wonder whether too ultrascientific an attitude in these drunken driving cases did not smack just a trifle of the pedantic and tend a bit to confuse the issue.

Let us be practical, let us not render our everyday decisions too difficult, especially in the eyes of our brethren of the law, and let us try to make our decisions on the basis of common sense plus practical professional experience and decide each case on its merits, instead of adhering too closely to a rule-of-thumb chemical test.

CHARLES K. REINKE, M.D., Oxford, Pa.

WATER INTOXICATION

To the Editor—I have read with interest the report of Helwig, Schutz and Kuhn in *THE JOURNAL* of February 26. Since they refer to some of our experimental studies (Smyth, F. S., Deamer, W. C., and Phatak, N. M. Studies in So-Called Water Intoxication, *J. Clin. Investigation* 12: 55 [Jan.] 1933), I feel justified in voicing an opinion regarding their interpretation. In the acute water intoxication induced experimentally by us in dogs, vomiting, not diuresis, was the more characteristic result. Water was given by gavage; no parenteral fluids were administered. In such cases the course was brief, the electrolyte loss was largely gastric hydrochloric acid, the result a relative alkalosis from acid deficit.

In contrast with these observations, the clinical picture described by Helwig and his co-workers is much more confused. The prolonged course with possible starvation, anesthesia, ketosis (or infection?) added potential acid fracture. No determinations of total base or sodium are offered to show that a base deficit did not also exist. The bleeding tendency suggests a probable loss of total electrolyte (both acid and base) hardly combated by 7,000 cc of water (proctoclysis, oral route).

I believe their citation shows that care should be exercised in obtaining a more complete panel of electrolyte determination before labeling a condition acidosis or alkalosis. Vomiting itself may cause depletion of both base and chloride; if largely gastric, chloride loss predominates. The predominance of chloride loss in the type of vomiting in dogs raised for a relative alkalosis in our experiments. In the rats used by Helwig and his co-workers, vomiting is not characteristic but, as Gamble and Ross have shown (Gamble, J. L., and Ross, S. G. The Factors in the Dehydration Followed by Pyloric Obstruction, *J. Clin. Investigation* 1: 403 [June] 1932), a gastric dilatation with electrolyte removed from the body has a somewhat similar effect. It may be that a relatively greater removal of base accounts for their experimental picture of acidosis.

As for the clinical picture, I believe great caution should mark the use of sodium bicarbonate unless it is certain that base depletion exists and that the use of proctoclysis and oral administration of large amounts of water with insufficient electrolyte is no protection against ketosis or blood dilution.

FRANCIS SCOTT SMYTH, M.D., San Francisco.

DOCTOR AND PATIENT

To the Editor—The close cooperation of doctor and patient has always been the condition of curing or preventing disease. The Greeks built temples to Aesculapius, and those who were healed at his shrines left votive offerings to the god. The association of priestly offices with medicine existed among primitive peoples. Today the patient places his life and future well-being in the hands of the physician or surgeon, in whom he has the fullest confidence. Full partnership of interest and purpose is the condition of successful medicine.

The patient gives up voluntary action and consciousness and lets the surgeon operate on his body to restore health. The man trusts his wife or his child to the power and guidance of the physician. The physician assumes the Oath of Hippocrates: "into whatsoever house I enter, it shall be for the good of the inmates." This relation between the doctor and those he has undertaken to guide and serve is the essential basis of the healing art. Every physician knows that without full cooperation and confidence of the patient he can do little to keep or restore health.

Mutual understanding and confidence is the essential condition of a physician's power to render real service to his patient. It was the most important and valued possession of the old-time family doctor. This is the reason that every conscientious and experienced doctor looks with disfavor on attempts to extend "state medicine" or "health insurance" into the lives and homes of patients. He knows that prescriptions and operations cannot give health, unless the daily life and fixed duties of the patient is to gain and keep health.

The purpose of the patient must be to make health the chief objective of his daily living. His trust in a medical adviser who will bring to his service all possible achievements of medical and general science that can help him is the only real health insurance. Doctor and patient must know and trust each other so well that they have a joint aim and can do perfect team work to attain it. The patient is the only one

who can know of all his symptoms as they arise. He must esteem his physician so highly that he will lay before him the most intimate feelings and desires for the success of their joint undertaking. Specialists may be needed and secured to meet special emergencies. But the personal physician who knows the patient on the one side and the general resources of medicine and the personalities of his professional colleagues on the other is the only one who can bring the full resources of medicine to the help of his patient.

The growth and recognition of preventive medicine make it ever more important that the whole life of the patient should be controlled by the requirements of health. It becomes more and more impossible that the lives and health of the people should depend on the working of a governmental or corporate machine which regards individuals simply as material for its impersonal working. The free association of patient and physician must never be placed in the control of financial interests or social dictatorships. The vital relationship of physician and patient should be guarded by all who understand the value of health.

EDWARD JACKSON, M.D., Denver

BLOODY TEARS

To the Editor—The short paper entitled "Bloody Tears. Bilateral Capillary Hemangiomas," by Dr. T. J. Dimitry (THE JOURNAL, February 26, p. 643), interested me greatly. Several years ago I had a patient who complained that he had bloody tears on one side. After careful examination, he proved to have suffered from occlusion of a posterior inferior cerebellar artery, which sometimes produces a unilateral paralysis of the sympathetics on the side of the lesion. This is associated with vasodilatation, dryness of the skin, enophthalmos and the Horner syndrome. Under such circumstances, doubtless a slight abrasion or inflammation of the conjunctivae resulted in a seepage of blood, which the patient called "bloody tears."

I feel that this adds interest to the case reported by Dr. Dimitry.

LLOYD H. ZIEGLER, M.D., Wauwatosa, Wis.

USE OF THIAMIN CHLORIDE IN POLY- NEURITIS AND CARDIOVASCULAR CONDITIONS

To the Editor—In the admirable expose of the therapeutic use of vitamin B₁ in polyneuritis and cardiovascular conditions, Maurice B. Strauss (THE JOURNAL, March 26, p. 953) justly emphasizes that striking as the results of vitamin B₁ therapy are in the cardiovascular disturbances arising from a deficiency of vitamin B₁, no effects whatever are to be expected in other types of heart disease with or without edema, in the edema of pregnancy toxemias, nephrosis and the like.

It may not be amiss to issue a word of caution with regard to the indiscriminate use of vitamin B₁ which is in vogue now, being advocated for a nearly endless variety of conditions. I am referring chiefly to intravenous injections of vitamin B₁. It has been shown (Narat, J. K., and Loef, J. A. Effects of Vitamin B₁ Concentrate, *Arch. Int. Med.* 60:449 [Sept.] 1937) that not only various extracts but in a lesser degree also synthetic crystalline products may provoke a drop in blood pressure; this effect is possibly attributable not wholly to impurities, histamine or choline. It follows that the depressor effect of vitamin B₁ preparations makes their intravenous administration undesirable in many conditions, particularly those associated with a low blood pressure. Vitamin B₁ is not a panacea, let us use it intelligently, lest it be discredited.

JOSEPH K. NARAT, M.D., Chicago

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

MYASTHENIA GRAVIS

To the Editor—What are the cardinal signs and symptoms of myasthenia gravis? Please outline the latest accepted modes of treatment with a word regarding prognosis.

M.D., Missouri

ANSWER—The cardinal signs and symptoms of myasthenia gravis are so characteristic that the diagnosis is not usually difficult. In the past, however, there has been considerable difficulty in diagnosing the disease in its early stages. In a majority of cases some trouble with the third cranial nerve is the beginning symptom, which leads to ptosis of the eyelids, either unilateral or more commonly bilateral, and some degree of diplopia. This may be the only sign which the patient shows. There is a tendency, moreover, for the weakness of the muscles to become more pronounced as the result of use, so that toward the end of the day the condition is worse than in the morning. Associated with the weakness of the muscles supplied by the third cranial nerve, one often finds weakness of the external rectus muscle, supplied by the sixth cranial nerve, and next in frequency there is involvement of the muscles innervated by the ninth cranial nerve, leading to dysphasia. A careful examination, moreover, will usually disclose bilateral weakness of the seventh cranial nerve, with some dulling of the patient's facial expression and inability to close the eyes tightly or to show the teeth widely. With this involvement of the motor branch of the fifth cranial nerve, difficulty in chewing or even inability to hold up the jaw frequently appears. It is characteristic for these patients to sit holding their lower jaw on their fist, with an expressionless face, often a nasal tone of voice, and with their eyes either partially or completely closed. Muscles involved less frequently are those of the neck and of the extremities. Some patients actually have difficulty in holding up the head. The weakness in the arms is usually generalized, without specific muscle involvement. In walking and getting up or down from a chair or bed the loss is a general one, although there may be partial footdrop. Easy fatigue of voluntary movements, without adequate cause, in some generalized activity is suggestive of myasthenia gravis. The disease is seldom seen before the second decade of life and is commonest in the third decade. Formerly it was considered that cases rarely occurred after the age of 30 and were almost unknown after 40. In the last few years a more careful study of the disease, as the result of its early diagnosis by the use of prostigmine, has led to the conclusion that older patients are not infrequent sufferers, even those in the sixth and seventh decades of life. In the older patients there is often a predilection toward dysphasia and dysarthria, with involvement of the neck muscles and generalized weakness.

The discovery of prostigmine and its remarkable effect on myasthenia gravis have led to its use not only as a diagnostic measure but also for treatment. In diagnosis the response in myasthenia gravis is rapid and remarkably complete and response in all other diseases is only slight. Viets and Schwab (*Neurol. England J. Med.* 213:1280 [Dec. 26] 1935) and later Viets and Mitchell (*ibid.* 215:1064 [Dec. 3] 1936) reported on the use of prostigmine as a test and devised a simple means of recording the data. Subsequently prostigmine has been used extensively in the treatment of the disease, having replaced in large measure most of the drugs formerly used, such as amino-acetic acid, ephedrine, benzedrine and potassium chloride. At first given subcutaneously or intramuscularly, prostigmine recently has been used in a tablet for oral administration with considerable success. Since the advent of this drug there have been few deaths. In a series of twenty-three cases reported by Viets, Mitchell and Schwab (THE JOURNAL, Dec. 11, 1937, p. 1956) in which the ages varied from 20 to 76, only one death occurred and that of a patient who did not keep up his daily intake of prostigmine by mouth. A 15 mg. tablet is used, sometimes with tincture of belladonna or atropine if the prostigmine causes abdominal discomfort. The effect of the drug moreover, may be slightly augmented in some cases by the use of 0.025 Gm. (three-eighths grain) of ephedrine three times in the twenty-four hours. Prostigmine is used from four to twelve times a day, the spacing of the drug being of considerable importance. Once the maximum dose is achieved patients have been con-

tinued on it for an indefinite time, in some cases as long as two years. Under this regimen about half the patients are able to resume their ordinary occupation, provided it does not require active muscular effort. Other patients are made fairly comfortable, although their life is much restricted. In cases in which there has been difficulty in swallowing, the oral pill may be given by stomach tube or, better still, an emergency injection of prostigmine intramuscularly may effectively tide over the crisis. Ampules of prostigmine should always be kept at hand.

HAIR COLOR AND DISEASE

To the Editor—To what diseases are blondes, brunettes and red heads disproportionately susceptible? Please include skin diseases. Is there a disproportion in the sickness and death rate of blondes, brunettes and red heads?

M D Massachusetts

ANSWER—There is apparently little information available on the subject of this inquiry. On page 102 of Draper's "Human Constitution" (Philadelphia, W. B. Saunders Company, 1924) it is stated that "among the tuberculous people 71 per cent of the males and 76 per cent of the females were light haired. Thus

cannot be accounted for as a Nordic or racial characteristic, since this group is only about 50 per cent Nordics. On page 240 of the same book is a table relating hair color to various diseases. As can be seen from the accompanying table, which gives the information contained in the one prepared by Dr. Draper, the number of patients was small, the results therefore must be viewed with conservatism and the percentages disregarded.

QUININE AND ATABRINE IN BREAST MILK

To the Editor—Are there any data on the excretion of quinine and atabrine in breast milk?

M D Mississippi

ANSWER—Terwilliger and Hatcher (*Surg. Gynec. & Obst.* 58:823 [May] 1934) have stated that "quinine may be detected in 1,500,000 parts of milk but the amounts present in very low concentrations slightly exceed those actually recovered. These authors administered five doses each of 300 mg. of quinine sulfate orally to two women and seven doses of 640 mg. to four women. Traces of quinine were detected in the milk in every case in one instance in the milk drawn thirty minutes after the administration. None was found in milk drawn as late as twenty-four hours after the administration of quinine.

According to Terwilliger and Hatcher the amount of quinine secreted in the mother's milk is too small to have any injurious effect on the nursing infant.

No references have been found on the excretion of atabrine in breast milk. However, it may be worth while to emphasize as was pointed out many years ago by Bucura (*Ztschr. f. exp. Path. u. Therap.* 4:398, 1907) that very few drugs have been found with certainty in the breast milk. Kunitz and Hatcher (*Excretion of Drugs in Milk*, *Am. J. Dis. Child.* 49:900 [April] 1935) studied the excretion of drugs in human milk and were especially interested in examining milk for morphine, codeine, salicylic acid, phenolphthalein, barbitals, sodium bromide and potassium bromide. They concluded that none of the above mentioned drugs except sodium bromide were present in the milk in an amount sufficient to indicate that the continued use of milk would injure a normal nursing child.

ERECTIONS AND FLATUS

To the Editor—A well developed and well nourished married male aged 43 for the past twelve years has been obliged to arise at 3 o'clock in the morning because of lower and intra abdominal gas pressure coupled with a severe erection. The erection precedes the pain symptom by about thirty minutes and the gas or pressure is relieved only after the subsidence of the erection after which considerable flatulence is passed. The only method by which relief is obtained is by walking the floor for two or more hours. This procedure has been repeated every night without fail for the past twelve years. A variable amount of generalized genital soreness persists for several hours because of the persistent erection and a certain amount of lassitude is present the rest of the day because of the loss of sleep. The sexual life is normal save that intercourse will aggravate the condition at the next session. Physical examination is essentially negative save for a few bouts of constipation and biliousness. The weight, temperature, blood pressure, blood urinalysis, Wassermann reaction, prostate and prostatic secretions are normal. Gastric analysis reveals total acids of 25 at the height of the digestive period. The patient does not belch or eruct gas. He is perfectly normal during the day.

M D Wisconsin

ANSWER—The patient is probably troubled with prostatitis in spite of the fact that rectal examination reveals a prostate within the limits of normal. The reflex gastro-intestinal disturbance is most likely on a basis of urinary retention and subsequent prostatic irritation. The patient should have a cystoscopic examination and probably subsequent prostatic massage if no local treatment is suggested from examination of the bladder.

INTRANASAL OPERATION FOR REMOVAL OF EXCESSIVE ETHMOID BONE

To the Editor—In a number of older persons a submucous operation on the nose done in early life failed to include sufficient removal of the superior portion of the perpendicular plate of the ethmoid bone. The result later has been elaboration of bony tissue along the rough cut end of this perpendicular plate with subsequent closing of one or both nasal fossae in their superior portions these portions being particularly narrow. Specialists have given me to understand that separation of the mucous membrane for a second submucous operation is impossible. In one instance pressing the offending portion of the ethmoid back into the (rebuilt) gave only temporary relief. Is there any accredited method for solving this problem? Is an open operation even at the expense of scarring the nose ever resorted to with success?

M D New York

ANSWER—An open operation in cases of this type is certainly not indicated. The thickened bone can be removed intranasally without the necessity of attempting to separate the agglutinated mucous membranes below it. The incision should be made along the lower border of the bony ridge, which is easily palpable and it may be placed in whichever side of the nose is most convenient or accessible to the surgeon. The mucoperiosteum is first elevated on the same side. Then it is necessary to expose the lower rough edge of projecting bone so as to permit a small curved periosteal elevator to peel off the mucoperiosteum of the opposite side. Naturally great care is necessary to avoid perforating the mucous membrane on that side. However, in most cases if the field has been injected with procaine hydrochloride and epinephrine there is very little bleeding and the progress of the instrument can be guided by direct vision. After the bone has been exposed on both sides it may be removed by using a sharp chisel, which is directed along a line parallel to the nasal bridge and at a safe distance below it. It is well in these cases not to attempt to break off too much bone at one time and it is recommended that it be bitten off piecemeal with the Freer Gruenwald forceps. In this manner one can safely approach the nasal bridge and even the olfactory region without the risk of accidentally fracturing the cribriform plate. At the conclusion of the operation one should have an intact mucosa on one side and a long incision in the mucosa of the other side running upward and backward. Since the

mucous membranes below the field of activity have not been touched, there is no need to pack the nose. Should there be persistent bleeding from the wound, it can be controlled by inserting on each side a cotton dental roll dipped in petrolatum, which is pushed up high under the bridge and left in place for twenty-four hours

RURAL LIFE AND MENTAL HEALTH

To the Editor—I have heard that the largest percentage of mental cases were to be found among the wives of farmers and this was caused by the fact that they lived isolated lives on remote farms and saw few if any people outside their immediate families. It has been stated also that with the coming of the telephone and the radio there was a material decline in this type of case because of the fact that these women experienced contacts with the outside world. Is this true? Where can I get the facts?

W E AUGHRIN HAUGH MD New York

ANSWER—The belief that mental disorders are more frequent in the wives of farmers arose largely from statistical studies reported from the eastern states forty or fifty years ago. More recent studies of the same nature tend to show no greater incidence of mental disorder in rural women than is found in the urban group. In fact, the pendulum seems to have swung in the other direction. However, no statistics seem available which are sufficiently general to cover the entire United States.

There is probably no single cause responsible for this change. While greater communication and contact through telephones, automobiles and radios may have contributed to this result, there have been other and even more profound changes in rural life which are equally, if not more directly, acting influences on mental health. First of all, improved rural sanitation has undoubtedly resulted in better physical health and this in turn has preserved mental health, then to be considered are improved rural medical care, elimination of drudgery and monotony by rural electrification, the utilities now available throughout the country, the newspapers, weeklies and periodicals and as far as women are concerned, one might also add clothes and cosmetics. Probably there are other less evident but equally potent factors, such as higher standards of living generally. It is difficult to point out any one or even several influences that have had a favorable influence all of which merely show how far so called mental hygiene is tied up with social as well as physical environment in every respect.

PAIN IN GROINS DURING PREGNANCY

To the Editor—During the latter half of pregnancy many women complain of pain or discomfort in one or both groins. I read some time ago that relief may be given to such patients by intramuscular injections of a preparation the name of which I have forgotten but which I believe was a vitamin product. In any event will you please advise me on the treatment of this condition.

MD Ontario

ANSWER—The discomfort in the groins that the patients complain of during the latter half of their pregnancy is probably due to the vascularity and hypertrophy of the ligamentous supports of the uterus. A properly fitting abdominal support will usually relieve this. There are no vitamin preparations which influence this condition.

It is possible that the physician is referring to muscular cramps of the thighs and legs, which occur during pregnancy. These cramps may be indicative of an insufficient calcium intake. It has been suggested that calcium gluconate put up in ampules containing 1 Gm, be given intramuscularly to increase the supply of calcium. These injections often help in the treatment of muscular cramps during pregnancy.

OVULATION—FORMATION AND FATE OF SPERMATOZOA

To the Editor—Do the two ovaries produce an ovum simultaneously? If so why is but one usually fertilized? What is the life of a spermatozoon when not expelled and if not expelled through intercourse what happens to it? How long is it till other viable spermatozoa are formed? Would the physical condition of the male germ just before fertilization have any bearing on heredity?

FRANK E WIEDEMANN MD Terre Haute Ind

ANSWER—Practically always only one ovum is expelled from one or the other ovary during each monthly cycle, hence only one ovum can be fertilized. Ovaries may or may not alternate in ovulation. Occasionally two ova are expelled at the same time or very close together and, if both are fertilized, twins result. Ovulation is controlled by an anterior pituitary hormone. Probably only one ovum is expelled because the amount of anterior pituitary hormone is sufficient to stimulate ovulation in only one follicle. If more anterior pituitary is injected into animals more follicles can be made to expel ova. In fact even during early pregnancy in rabbits it is possible

to induce ovulation by the injection of anterior pituitary. The ova thus expelled are normal and possess the capacity for fertilization and development.

Spermatozoa are capable of living a few days in the testicles and seminiferous tubules. If coitus or ejaculation does not take place within a reasonable length of time, the spermatozoa in the genital tract die just as any other type of cell does. Spermatozoa are constantly being formed in normal men. At the time of an orgasm, not all the sperm in the genital tract are expelled at one time. Some deep down remain there or reach higher parts. It is probable that, when defective sperm fertilize normal ova, miscarriages result. In these cases the fetuses may or may not be normal. Some abnormal conditions are hereditary and, although sperm transmit some of these abnormalities, the gross physical condition of the sperm may nevertheless be normal. Definitely abnormal sperm are probably incapable of fertilization.

AUTONOMIC IMBALANCE

To the Editor—A man aged 45 has complained for fifteen years or more of a constant burning sensation in the left lower quadrant discomfort and slight distention. He has weakness and there is some perspiration of the hands. There is no nausea vomiting or melena. The entire examination of the chest is negative. There are no masses in the abdomen. There is no rigidity. A series of roentgenograms of the gastro-intestinal tract including the gallbladder was negative. Two blood tests showed 5 000 000 erythrocytes and 90 per cent hemoglobin. Leukocytes numbered 7 800 with 1 per cent eosinophils, 45 per cent polymorphonuclears, 47 per cent lymphocytes and 7 per cent mononuclears. The Schilling count gave no myelocytes no juveniles 8 per cent basophils and 37 per cent segmented cells. The Wassermann reaction was negative. Sometimes the skin appears slightly dusky or tanlike. What must I consider?

MD, Massachusetts

ANSWER—A clinical condition that has persisted over a period of fifteen years and has produced no demonstrable structural changes is likely to have its origin in a functional disturbance. The patient described might well fall into the group said to suffer from autonomic imbalance of the vagotonic type. With a normal total leukocyte count and a lack of abnormalities the differential count shown does not seem particularly significant. There is no unanimity of opinion regarding the importance placed by Schilling on small variations in the differential count. It is interesting to note however, that Schilling considers a lymphocytosis with a normal white count a diagnostic feature in vagotonic states.

Schilling cites the following as typical of "vagotonia": total white count, normal, basophils, 0, eosinophils, 4 per cent, neutrophils, 45 per cent, lymphocytes, 45 per cent, monocytes, 6 per cent, myelocytes, 0, juveniles, 0, stab cells, 1 per cent, segmented cells, 44 per cent. With the exception of a slightly higher percentage of eosinophils, this count shows a striking resemblance to the one exhibited by the patient under discussion.

PAROXYSMAL NOCTURNAL DYSPNEA OR CARDIAC ASTHMA

To the Editor—I should appreciate a discussion from the points of view of pathologic physiology and of therapy of the symptom complex of paroxysmal nocturnal dyspnea encountered in cases of hypertensive cardiovascular disease.

PHILIP SIEGEL MD Beacon N Y

ANSWER—Cardiac asthma is the preferred term to describe the attacks mentioned. R S Palmer and P D White (The Clinical Significance of Cardiac Asthma, THE JOURNAL, Feb 9, 1929, p 431) and Sylvester McGinn and P D White (New England J Med 207 1069 [Dec 15] 1932) have reviewed the largest collection of these important cases. The symptom complex is truly asthmatic in nature and is fundamentally of cardiac origin. The exact mechanism is not known but it is apparently induced most often by failure of the left ventricle to respond to an increased functional demand. It occurs so frequently, though not necessarily, at night with the patient asleep, that it appears to be associated with an increase in the volume of blood in the pulmonary field as the result either of the effect of gravity in the recumbent position or of insufficiency of the left ventricle, or to both of these factors. As a result of this reduction of vital capacity the respiratory center is subjected to excess reflex stimulation and as sleep becomes lighter the nervous mechanism gradually becomes freed from its normal sedation and at a critical point responds producing violent dyspnea.

The immediate treatment is to reduce the sensitivity of the respiratory center, which is done specifically by morphine. Preventive treatment is the same as that of chronic congestive heart failure namely, rest reduction of fluid intake and digitalis. The presence of the symptom complex indicates that the therapeutic regimen has been inadequate.

COITUS DURING MENSTRUAL PERIOD

To the Editor—Will you kindly give me a detailed discussion on the subject of intercourse between husband and wife during her menstrual period. What are the dangers if any? Will too much sexual excitement produce pelvic congestion with noticeable symptoms and should this result in abnormal menstrual flow? If such is the case what are the diagnosis, symptoms and treatment?

MD Maryland

ANSWER—There are no statistics to be found in medical literature on this question and practically no discussion. As an almost universal rule coitus is not deliberately engaged in during this time, mainly for esthetic reasons. The German sexologist Rohleder actually advises coitus on the last day of the period, on the theory that it is a good time for impregnation. Investigations on the behavior of spermatozoa in the female genitals have demonstrated live spermatozoa in the uterus during the menstrual period. Thus in one case at least the menstrual blood was not inimical to the vitality of the spermatozoa. Coitus during menstruation is so rare that there are not a sufficient number of cases recorded from which general deductions can be made.

NEOARSPHENAMINE IN UNDULANT FEVER

To the Editor—I have recently been informed of a physician who has successfully treated several cases of undulant fever by intravenous injection of nearsphenamine. I have been unable to locate any literature on this type of treatment. Is there any rationale for nearsphenamine in undulant fever?

MD Oregon

ANSWER—Conflicting reports have appeared in medical literature regarding the efficacy of nearsphenamine therapy in undulant fever. Simpson (*Ann Int Med* 4 238 [Sept.] 1930) found this method to be ineffective. The common denominator of the methods of treatment which have proved most effective in the management of undulant fever, such as Brucella melitensis vaccine, brucellin (Huddleson), typhoid vaccine and artificially induced fever therapy, has been the production of a febrile response. There does not appear to be any rational basis for the employment of nearsphenamine therapy in undulant fever.

OSTEOMYELITIS AND OSTEOPOROSIS AFTER INJURY

To the Editor—Will you be kind enough to let me know whether a man could develop an osteomyelitis or at least an osteoporosis showing up in a roentgenogram if he was injured Aug. 20, 1937, at 1:30 p. m. and came to a physician August 23 with an infection of the left index finger.

NATHAN TANDET MD New York

ANSWER—It is possible that an osteomyelitis might develop in three days following an injury but it is quite unlikely that osteoporosis would be demonstrable in an x-ray film three days after an injury. More time than that would necessarily have to elapse before the calcium content of the bone could be sufficiently reduced to cause this phenomenon to be present.

ADULTERATION OF MILK AND GOVERNMENT STANDARDS

To the Editor—Is there any simple test to show whether or not there is any powder in milk to make it thick or cream appear thicker?

MD, Ohio

ANSWER—There is no simple test to detect adulteration of milk or cream. A publication of the department of agriculture of the state of Ohio entitled "Ohio Food, Dairy and Drug Laws and Sanitary Regulations and Standards" provides considerable information about the legal requirements for milk and other dairy products.

BENZOIC AND SALICYLIC ACIDS WITH CALAMINE AND PHENOL

To the Editor—Would calamine 1 drachm (4 Gm) and phenol 10 grains (0.65 Gm), together with benzoic acid 1 drachm (4 Gm) and salicylic acid one-half drachm (2 Gm) as much as will suffice with a plain ointment base have any chemical or physiologic incompatibility or would this be in any way undesirable? Do you think the calamine and phenol would detract from the value of the benzoic and salicylic acids?

MD Georgia

ANSWER—There is no incompatibility in the prescription.

EXCESSIVE BEER DRINKING

To the Editor—Is there any known remedy for excessive beer drinking? Can this remedy be administered without the patient's knowledge?

STANLEY R. NOWAK MD, Adamstown Md.

ANSWER—No reference has been found to any recognized specific remedy for excessive beer drinking. The sanatorium treatment, which has been extensively used for chronic alcoholism, cannot be applied without the patient's knowledge.

Council on Medical Education and Hospitals

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

Thirty Fourth Annual Meeting held in Chicago Feb. 14 and 15, 1934

(Concluded from page 1309)

DR J. W. BOWERS, Fort Wayne, Ind., in the Chair

THE FEDERATION OF STATE MEDICAL BOARDS

FEBRUARY 15—AFTERNOON

SYMPOSIUM ON PROMULGATION OF REGULATIONS AUTHORIZED BY LAW

Nature and Scope of Regulations, Authority for Promulgation, Manner of Promulgation, Proof of Regulations in Court Proceedings

DR ROY B. HARRISON, New Orleans. In the light of legal principles, we may conclude that a state board of medical examiners may be given the authority to enact only such rules and regulations as relate directly to the subject matter covered by the legislative act and which are reasonably necessary to carry that act into effect. In what detail the legislature must express the intentions sought to be accomplished by the law is a question of fact to be determined, in the event of controversy, by the courts. The question of whether the courts should give a liberal or narrow construction to an act of this kind touches on a much broader subject. From our point of view, the greater the detail in which the legislative intent is expressed, the less the risk of a court throwing the law out as an unconstitutional delegation of legislative power.

Most of the medical practice statutes enumerate the subjects in which the applicant must stand an examination and the educational standards he must meet in order to qualify for the practice of medicine. Under this type of statute, the duty of the board is primarily that of preparing examinations in the designated subjects and ascertaining that the other requirements of the law are complied with. The constitutionality of this type of statute has been upheld by the Supreme Court of the United States in the cases of *Dent v. West Virginia* and *State Board of Medical Examiners v. Fife*, the latter of which involved the statute of Louisiana.

It has been held that the legislature does not have the right to vest in any board the unqualified and unrestricted power to determine who shall engage in any profession, trade or business. Between this extreme case and the ordinary type of statute is a vast middle ground, within which statutes may be held to be constitutional or unconstitutional, depending on the extent to which the legislative will is expressed in the statute and, to a lesser degree, on whether any particular court applies a liberal or a narrow construction to the act in question.

The second question is the power of regulation that has actually been granted to the board of medical examiners. For obviously, the legislature may not have seen fit to give to the board of examiners as full authority and power on this subject as it might lawfully do. Under the Louisiana law the type of regulations contemplated are such rulings as the board finds necessary to enable it to operate efficiently and to assure conformity in the execution of the law. This act does not contemplate the adopting by the board of regulations imposing any fundamental requirements. Under a law less specific than the Louisiana type of statute, the regulations of the board of examiners would of necessity, cover a greater scope.

It might seem desirable to make the statutory law as general as possible, so that the board of examiners should as a body of experts, have the power to determine from time to time some of the fundamentals of the subject. The only disadvantage of this type of law is its constitutional uncertainty.

Most state constitutions contain specific requirements as to the method of promulgating laws adopted by the legislature. The most usual requirement is by publication in the official journal. In any instance in which the law has specifically provided a method of promulgation, it is clear that such method must be followed in order for the rules and regulations to have legal effect. The supreme court of Louisiana has held that rules and regulations of the board of health need be promulgated only in the manner required by the legislative act authorizing their adoption and that the constitutional provision prescribing the method of promulgating statutes is not applicable. In the past ten years, in lieu of printed booklets, we have multigraphed forms made in the office, for specific applicants, such as "Rules and Regulations Governing Examination in Medicine," "Rules and Regulations Governing Reciprocity" and "Rules and Regulations Governing Endorsement of Applicants to Another State." Approximately 90 per cent of applicants for examination in Louisiana are graduates of either Tulane University or the Louisiana State University Medical Center.

From time to time as important rules and regulations are adopted by our board, especially those referring to requirements for examination and medical licensure, copies are sent to the deans of both universities with the request that they transmit the information contained therein to the medical students. About a month prior to our June meeting, multigraphed forms containing information relative to our requirements for examination, states with which Louisiana has reciprocity and other material, are posted on the bulletin boards of the medical colleges in Louisiana, and it has been our practice to have the presidents of both of the senior medical classes call at our office to be given detailed information for the benefit of the members of the graduating classes. We have found this method of promulgation very effective in Louisiana.

To prove the adoption of any resolution by a state board or commission, it is necessary to produce in court a copy of such regulation certified as correct by the secretary of the board or commission. We feel that every examining board should have a legal adviser. Our experience has shown it to be advantageous for a state examining board to have its own attorney. For many years our board has had its own special attorney, in addition to the public attorneys, and we feel that we would have been much handicapped had we been unable to employ our own counsel.

Formulation and Promulgation of Regulations Authorized by Law for Medical Licensure

DR THOMAS J. CROWE, Dallas, Texas. Only executives of long experience are aware that there are more incompetents and impostors now preying on sick human beings—attempting to practice medicine—than ever infested any other profession or occupation in the history of the world. Only an executive of long service could possibly know how urgently necessary it is that the reputable medical profession and the state boards should get together and plan to expose effectively the incompetents and impostors, and to formulate and secure if possible the general adoption of a uniform medical practice act, so skillfully constructed and so clearly defined that it cannot be misinterpreted even by a layman, which will effectively stop the medical pirates now victimizing human sufferers. Such a general law would be more effective than the forty-eight different statutes we now have to deal with. Every essential, fundamental regulation for licensure should be clearly, completely, and specifically stated in the statute so that it cannot be misunderstood or misinterpreted even by a child. I do not believe that discretionary power to modify or waive qualifications essential to the safety of the public should be delegated to an irresponsible, temporary appointive organization. The phraseology of a law governing such fundamental regulations, particularly in defining what constitutes the practice of medicine or the treatment of a disease or disorder, moral turpitude, unethical practice and malpractice, unprofessional conduct and so on, should be so completely defined as to eliminate any possibility of misinterpretation.

To clarify the point I shall quote the definition of the practice of medicine, as defined in the Texas act. The definition reads as follows: Who shall be regarded as practicing medicine? 1 "Any person who shall publicly profess to be a physician or surgeon and shall treat or offer to treat any disease or disorder, mental or physical, or any physical injury or deformity by any system or method or to effect cures thereof, or 2 Who shall treat or offer to treat any disease or disorder, mental or physical, or any physical injury or deformity by any system or method, and to effect cures thereof and charge therefor, directly or indirectly, money or other compensation." Notwithstanding our definition seems to be as nearly fool proof as it was possible to make it, we sometimes have trouble in getting a conviction because of lack of completeness, because of our failure to cover the use of the hands in making so called adjustments and the like. Since the most flagrant of our violators assert that they never professed to be a physician or surgeon, that they do not give medicine of any kind, that they do not treat a disease or disorder, that they simply adjust the spine, it is not always possible to convince all jurors that one who does not profess to be a physician or surgeon nor treat a disease or disorder nor give medicine of any kind, only adjust the spine, should be convicted of practicing medicine. Our law is also deficient in that it fails to define the acts which constitute moral turpitude, malpractice, unethical practice and unprofessional conduct. Unless all these acts are completely defined in the statute, the outcome of a case must depend on the opinion of the trial judge, as to the intention of the legislature which enacted the law, and on the interpretation of the jury as to what constitutes a violation of the law.

I believe that education of the public to realization of what modern scientific medicine has actually done for suffering humanity in the last hundred years is far more convincing and important to the peoples of the world, and that such realization eventually will more certainly, completely and permanently stop medical piracy and racketeering than the most cleverly conceived statute for the inhibition or suppression of activities which the unlicensed, incompetent practitioner, his high powered attorney, his promoters and his friends refer to as malfeasable rights.

In promulgation of its law and its rules and regulations, the Texas board publishes each year, on expiration of the registration period, a "Handbook of Information, with Official List of Authorized Practitioners of Texas for the Year and Extracts of the Law" a copy of which is mailed to every district and every county medical society of the state (134), every district attorney, every county attorney, legislators, Better Business bureaus (500 in the state), state, county and municipal officers, inquiring insurance companies and all who seek information on the law and the rules and regulations of the board, inclusive of the newspapers.

We have a large register, indexed in 120 subdivisions, containing a complete record of every practitioner licensed in Texas since the organization of the present board in 1907, a record of all examinees of this board since 1907, with grades made, general average, and showing whether licensed or rejected, and number and date of license, and a record by serial number of the name of every practitioner to whom a registration permit has been issued since 1932, when registration was adopted.

DISCUSSION

DR WILLIAM C. WOODWARD, Chicago. There seems to be a confusion in the minds of our secretaries and many laymen as to the difference between our state laws and the regulations made by virtue of those laws. A legislature cannot delegate to any subordinate body its legislative powers. That rule was rather strictly adhered to until say within the last quarter of a century within which time there has grown up a great body of what is known as administrative law. No legislature could write into the statutes every detail of administration and enforcement necessary to insure success. So the courts have recognized that a legislature may delegate to an official body that is charged with the enforcement of the law the duty of

putting in details under the law that are necessary to the accomplishment of some general purpose set out in the statute. Under some authority of that kind our several examining and licensing boards operate. So long as the examining and licensing board promulgates regulations within that limit, the limits necessary to make the law effective, those regulations are valid. The moment the board oversteps the limits and undertakes either to enlarge the medical practice act or to diminish it, the regulation is void. I should divide the regulations that a board may promulgate into two classes. One class has been referred to here as the regulations that are limited in their effect to the board itself. I do not believe that any special authority is necessary to enable a board to promulgate regulations of that sort. The regulations of the second class are those that are intended to govern persons who have no official relation to the board or who have just established official relations of some kind in order to obtain licenses or in order to bring about the revocation of a license or something of that kind. Those regulations must have the certainty of a statute.

The statute that is promulgated by an examining and licensing board, a board made up of scientifically well trained men, ought to be more certain than is the type passed by a state legislature or by Congress. Undoubtedly, in the formulation of those regulations the services of a lawyer are indispensable. In the first place the regulations must be kept within the limits prescribed by the statutes. The regulation must be accurately fitted into the regulations that are already in force. After everything has been phrased in proper form, the regulation must come before the board and be voted on in the ordinary course of business and adopted by the board by the required majority, whatever that may be, all of which should appear in the minutes of the board. It may be desirable to keep a separate record of those regulations. If that separate record is a record that is authorized by law, it may be admitted into court as evidence. Otherwise the best evidence is the minutes of the board that can show just what the regulation is at any given time. There will be little difficulty in certifying to the regulations of a given board within the state in which that board functions. A greater difficulty will arise in connection with applications for licenses in other states, by licentiates of a given board who desire to prove in some foreign state just what the regulations were in the home state at the time of the issue of the license. I think no very exact requirements have been made regarding the certification of copies of the regulations promulgated by some foreign examining and licensing board. If the matter comes into court, the regulations will probably have to be in the form in which they can be certified, in the first place, by the secretary of the board, under the seal of the board, and then certified by some proper court and state officer in order to satisfy the requirements of the other state.

Any one who proposes to apply for a license to practice in a given state ought to be able to turn to a given official record or to obtain from the board an official copy of that record telling him exactly what is required of him. That involves publication somewhere. The best way, in the absence of any express requirement, is publication in some newspaper or in some official state publication provided for the publication of records of that sort. The regulations referred to should cover the form of application, the time of examination, the standards to be set by examination, what constitutes an accredited school, what schools will be recognized and what schools will not be recognized. Possibly they should elaborate on the details looking toward the suspension and the revocation of licenses, which, after all, constitutes one of the functions of the board that is most likely to be called into question in court.

The authority of the boards to make regulations has, I think, been rather loosely construed in many places. To indicate the nature and extent of the authority and the limitations on the authority in some particular cases I will refer to the statutory provisions in several of the states. In Oklahoma and in Oregon there is an interesting provision providing that the board shall increase the educational requirements for license as educational requirements in other states are increased. Here is a provision in Pennsylvania: "The department of public

instruction be and hereby is authorized and directed annually at least three months prior to the end of the current fiscal year, to fix the fees to be charged by the several professional examining boards within said department during the ensuing fiscal year." That must be done within a stated period or it isn't effective. South Dakota has a very elaborate system of practice. The board there has the power to license and regulate the practice of medicine and surgery within this state and to make all rules and regulations which may be necessary or expedient to that end." But as in North Carolina when we examine the context we find that the power of the board is much limited. Utah has an elaborate scheme and apparently without any statutory authority, has undertaken, as North Carolina has done, to recognize the officers of the Army Navy and Public Health Service, and diplomates of the National Board of Medical Examiners. A question recently arose in connection with licensure, where an attempt was made to impose practical examinations in connection with reciprocity. That was a case in which reciprocity was authorized, as may be, and the boards agreed between themselves that they would not reciprocate except after a practical examination. I think there is a grave question as to how far that can go. If the board has discretion as to whether it will not license a person by reciprocity, it may impose such a requirement, but when the law fixes the conditions under which reciprocal licenses shall be issued, according to at least one decision, the board cannot go beyond that. I have in mind cases in which the boards have undertaken to impose citizenship requirements in the absence of anything whatever in the statute authorizing that to be done. It would seem as if the federal government has not placed any prohibition on the incoming of foreigners and if the state legislature has not imposed citizenship requirements, that is assuming a state legislature can impose citizenship requirements—and concerning that there is serious doubt—certainly it is hardly likely that a board itself can act in such an important function.

DR CROWE: Is it true that a board must classify the colleges on its own account, and it cannot take an outsiders classification?

DR WOODWARD: In the state of California that question has arisen, and the recognition of the classification of colleges by the American Medical Association has been sustained. Generally speaking, however, the board must establish its own standards and enforce them. It can if it sees fit establish the same standards that the Council on Medical Education and Hospitals established, and it can take evidence of what the Council has done.

The Basic Science Law Its Purpose and Effect on Registration and Reciprocity

DR JULIAN F. DU BOIS, St. Paul: Minnesota's law requires that before a candidate may appear before any board for examination whether medical, osteopathic or chiropractic he must present a certificate in the basic sciences. If a diplomate of the National Board, his part I is accepted in lieu of a basic science examination. The law has worked a hard hip on the doctors because it has reduced reciprocity for those with Minnesota licenses many boards feeling that since we cannot admit their men without a Basic Science Certificate they cannot admit our men without an examination. Since 1937 we have admitted 173 doctors by reciprocity and seven by three by National Board certificates, and we hope that before many years our difficulties will be ironed out and reciprocity again general. We do not blame these boards but we do feel that the standards of healing have been raised in our state and our public therefore benefited. Before the passage of our basic science and registration laws investigations and prosecutions were carried on by various law enforcement officers and we do not have an accurate record of this work, although we know it was very haphazard and limited. In the ten year operation of this law we have had 405 investigations and 100 court cases with 116 convictions, ten found not guilty, 10 not indicted, and ten court cases dismissed. These cases have been against the unlicensed, the chiropractors, the osteopaths, and sorry to say against some medical men. In 1923 a law

162 osteopaths and 493 chiropractors registered. In 1937 we had 160 osteopaths and 398 chiropractors registered. But this doesn't tell the whole story, as during the years from 1922 to 1927 we averaged thirty-nine new chiropractic licenses and eight and one-half new osteopathic licenses a year, while in the ten years of the basic science law we have averaged 41 new osteopathic and 14 new chiropractic licenses a year. From this you can see that investigations and prosecutions have been regularly carried out and under the supervision of the Minnesota State Board of Medical Examiners, cultists have decreased and better care has been given the sick. The doctors like this law, the public seems satisfied, prosecutions and investigations have been ably carried on, and cultists have decreased. So we feel that the tenets of a public health law have been fulfilled.

DISCUSSION

DR HAROLD RAYNS, Albany, N. Y. At other times I have had occasion to take issue with the proponents of the basic science law, but over a period of years I have come to learn that in some jurisdictions there is a great need for such a law. In the few states where there is no legislation authorizing the practice of chiropractors, naturopaths and similar cultists, I believe that a basic science law is unnecessary. However, in the majority of states where legislation does authorize cult practice, I think the evidence is cumulative that the value of the basic science law is sufficient to overcome its nuisance value. However, it is not necessary to have a basic science law in order to have an annual registration, in order to have funds for enforcement, or in order to have adequate enforcement. In New York State, where we have no basic science law, I believe we have other statutes under the medical practice act which are comparable to those that are working so efficiently in Minnesota. The proponents of the basic science law in states where cultists have been authorized to practice make out an excellent case for the law and that the administration of this law in the hands of such men as Dr. Du Bois has done much to break down any former opposition.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL April 16 page 1309

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS. Parts I and II. Examinations will be held in all centers where there is a Class A medical school and five or more candidates who wish to write the examination. May 9-11 (limited to a few centers). June 20-22 and Sept. 12-14. Ex. Sec. Mr. Everett S. Elwood, 225 S. 15th St. Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY. Oral examinations for Group A and B applicants will be held at San Francisco June 13-14. Sec. Dr. C. Guy Lane, 416 Marlboro St. Boston.

AMERICAN BOARD OF INTERNAL MEDICINE. Written examination will be held at various centers of the United States and Canada Oct. 17. Final date for filing applications is Sept. 1. Chairman, Dr. Walter L. Biering, 406 Sixth Ave., Suite 1210, Des Moines, Iowa.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY. General oral clinical and pathological examinations for all candidates (Groups A and B) will be conducted in San Francisco June 13-14. Sec. Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY. San Francisco June 13. Washington D. C. Oct. 8. Oklahoma City Nov. 15. All applications should be filed immediately and case reports in duplicate must be filed not later than sixty days before the date of examination. Sec. Dr. John Green, 3220 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY. Chicago June 10-11. Sec. Dr. Tremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY. San Francisco June 10-11. Sec. Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PATHOLOGY. Philadelphia May 5-6. Sec. Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS. New York City May 3-4. San Francisco June 12. Detroit October. Rochester N. Y. November and Oklahoma City November 15. Sec. Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY. San Francisco June 11. Sec. Dr. Walter Freeman, 1028 Connecticut Ave., Washington D. C.

AMERICAN BOARD OF RADIOLOGY. San Francisco June 10-12. Sec. Dr. R. L. Kirklin, 102110 Second Ave. S.W., P.O. Box 107, Minneapolis.

AMERICAN BOARD OF UROLOGY. San Francisco June 11-13. Sec. Dr. Gilbert J. Thoma, 1009 Nicollet Ave., Minneapolis.

Book Notices

Intern Education and Supervision. Prepared by a Joint Committee of the Committee on Medical Education of the Ontario Medical Association, Committee on Medical Education of the Canadian Medical Association and Department of Hospital Service of the Canadian Medical Association. Paper, Pp. 44. Toronto: Canadian Medical Association, Department of Hospital Service. [n.d.]

"The internship has become a very essential part of the clinical preparation of the student in medicine." "The employment of interns implies definite obligations on the part of both the interns and the hospital and its staff." "From the viewpoint of the intern he is there to learn, and he is giving one or more years of his time and is serving with little or no compensation beyond his maintenance. The hospital and its staff therefore should provide adequate facilities for clinical and laboratory training and should give the work of the intern proper professional supervision." These quotations from the introduction to this booklet fairly describe its scope and purpose. Among the topics treated are the purpose of the internship, the medical staff should be intern minded, the induction of interns to their new duties, programs for the instruction of interns, facilities necessary for the interns' work, affiliations with other institutions for special services, the medical library, postmortem examinations, outpatient department, history taking, staff meetings, the social aspects of medical care, medical ethics, and supervision of the interns' health. There is also a discussion of the supervision of intern training and its relationship to medical licensure. This booklet should prove invaluable to hospitals contemplating the establishment of an intern service.

Practical Birth Control. A Guide to Medically Approved Methods for the Married. By Rita Irwin and Clementina Paolone, M.D. Cloth. Price \$1.75. Pp. 172 with 5 illustrations. New York: Robert M. McBride & Company, 1937.

In the preface the authors discuss frankly their attitude on the controversial subject of birth control. They feel that before deciding on pregnancy any woman with diseases of the general system—serious heart or kidney conditions, diabetes, tuberculosis—should consult a physician. The list of these diseases may be increased by including nervous and mental diseases or insanity. Therapeutic contraception in their opinion is warranted for medical reasons when the examination indicates repeated difficult deliveries and when defects and deformities exist. The well known argument that pregnancies should be spaced receives attention, the authors venture the statement that "three babies die who are born less than two years after the last child for only two who die when the interval is longer." Such questions as the age of the mother and the economic question as to the number of children that may be cared for are also considered leading up to the classic guide to parenthood. "The wise mother and father will plan to have as many children as can be safely carried, safely borne and adequately reared." From this point on the authors launch into the subject in typical pedagogic manner, giving the definition of birth control and the history of contraceptive practices to the present time.

In common with many books addressed to the public, the authors rather 'talk down' to the readers. The book, however, does contain information, particularly on how birth begins, that is well epitomized and may be a good source of reference for physicians who wish to cite references to persons contemplating marriage. The discussion of unreliable or harmful methods may be of value to any physicians who wish to impart information on therapeutic contraception, although the figures quoted in some cases lack confirmation. The authors point out that the majority of the medical profession condemn the rhythm method as unreliable and join the chorus of others who state that its effectiveness has not been proved by scientific research.

It is interesting to note that the use of condoms is among the partially reliable methods. This is based on the work of Vogt published some years ago who asserted that 45 per cent of them had imperfections. Some of the statements which are made are subject to question particularly when it comes to percentages of failures. The authors feel that the use of chemicals or spermicidal suppositories and jellies alone, always

involves the element of chance. The approved method is the jelly-pessary procedure. Rather naive is the last sentence of the discussion on the approved method.

From what has been said about the contraceptive measure approved by medical leaders, it is evident that the pessary jelly method is harmless and reliable can be prescribed in all cases where birth control is medically indicated except under unusual circumstances and is satisfactory from the point of view of personal considerations of wife and husband. Proof has been advanced that the method has been successful in preventing pregnancy 93.97% of the time.

The authors emphasize the value of consulting a physician but continue that if one would rather not go to the regular physician one may obtain information from the American Birth Control League concerning physicians competent to give advice. Reference is also made to lay clinics, contraception clinics and finally warning against commercial clinics, promoted in the interest of proprietary products. In the latter class, of course, one finds much quackery.

All in all the book is one that may be read with profit by those who are entitled to information on this subject. It is clearly printed and is not too long a discourse. The authors are to be commended in their desire to be particularly fair and not too enthusiastic on this subject.

Lehrbuch der biologischen Heilmittel. Von Dr. med. Gerhard Madhaus. Abteilung I. Heilpflanzen. Bande I, II und III. Registerband. Paper. Price 92 marks per set. Pp. 902, 983, 1884, 1885, 2864 with 1180 illustrations. 144. Leipzig: Georg Thieme, 1938.

This treatise is perhaps the most extensive and complete work on medical plants ever published in any language. The author has compiled in systematic and readily accessible form information on all the common plants used in therapy. The descriptive sections are unsurpassed, in all some 444 plants, parts of which are or have been included in various pharmacopoeias and dispensaries, are described in detail. The botanic name and its etymology are given, the lay designations in all or most of the languages of Europe (and even in a few of the dialects) are set down in addition. A map showing the distribution of the plant is included in each case, followed by an excellent halftone or colored illustration of the plant itself. Botanic and historical data are given, followed by a discussion of the pharmacologic actions and therapeutic uses. Typical prescriptions containing the drug are set down at the end of each description. Though some of the general material will be chiefly of historical interest, other parts are devoted to valuable discussions of recent developments in phytochemistry and the like. Especially useful are the sections devoted to the occurrence in plants of various chemical substances of pharmacologic interest. References to the literature, ancient and modern are given in profusion. An extensive index in a separate volume completes the work, this index is divided into four sections: Latin botanic names, common German designations, chemical substances and therapeutic index. These books, representing the culmination of a lifetime of labor devoted to the subject by the author, are invaluable for reference.

Food Technology. By Samuel C. Prescott, Sc.D., Dean of Science and Health Department of Biology and Public Health, Massachusetts Institute of Technology, and Bernard E. Proctor, Ph.D., Associate Professor of Food Technology and Industrial Biology, Massachusetts Institute of Technology. Cloth. Price \$5. Pp. 630 with 70 illustrations. New York & London: McGraw-Hill Book Company, Inc., 1937.

This book constitutes a reference work covering many phases of food technology which have not heretofore been generally available to the average person. The names of the authors have long been associated with scientific contributions to the processing of foods and the book represents the fruition of many years of experience. There are twenty-two chapters which provide technical information regarding the commercial preparation of the most important foods of both plant and animal origin. Wheat, corn and minor cereals, vegetables, fruits, sugars, meat, fish and poultry products, milk and dairy products, spices, condiments, vegetable oils and fruit juices are discussed in detail. There are also chapters covering adequately in general terms the commercial processes of baking, canning, refrigeration and dehydration. The book tells all about how foods are produced and prepared for the market and it tells the reasons for each process. The book should be valuable to food

manufacturers and all those whose work is concerned with supervision or inspection of food supplies. Although it provides considerable technical information, it is written in an understandable style. The authors state that a more complete technical discussion of certain of the food industries is contemplated in the near future.

The Human Body. By Logan Clendening, M.D. Third edition. Price \$3.75. Pp. 443 with 106 illustrations by W. C. Shepard and J. L. Beronius and from photographs. New York: Alfred A. Knopf, Inc., 1937.

Since its first publication, some 200,000 copies of this book have been distributed to American readers. In his preface Dr. Clendening points out that he has revised almost every page and that the chapters on nutrition and the ductless glands, particularly needed complete recasting to bring them into line with the rapid progress that is being made in these departments. He also added a separate chapter on the infectious disease. His philosophy on medical matters has not considerably changed so that the original philosophy and a number of the original jokes still remain. The book is illustrated mostly with line drawings taken from illustrations in various medical works. The style of the author and his humanness make his book of the human body the attractive work that it is. His chapter on the relations of the mind to the body is a forthright and honest analysis of the power of suggestion and its effects on human beings, which would overcome a good deal of superstition and quackery if it was more widely read and distributed. For a general public audience, the chapters on pathologic changes and on tumors might have been more simplified. For instance, the author says "In the internal organs the result of thrombosis or of an embolus is an infarct. An infarct is an area of tissue which has undergone or is undergoing necrosis, more or less complete as a result of arterial thrombosis to the part." Notwithstanding the fact that he has previously defined thrombosis, embolism, infarct and necrosis, this statement could have been written in more understandable English. Nevertheless, even with these slight faults, the book merits even greater circulation than it has already had.

Volume Jubilaire en l'honneur de Monsieur Louis E. C. Dapples docteur en droit de l'Université de Lausanne, président du Conseil d'administration de Nestlé et Anglo-Swiss Holding Company Ltd pour son soixante-dixième anniversaire. Boards. Pp. 804 with illustrations. Nestlé & Anglo-Swiss Holding Co. Ltd, 1937.

Louis Dapples was president of the board of management of the important world-wide Anglo-Swiss Holding Company, Ltd. This book was intended to be a jubilee volume in honor of the seventieth anniversary of the company president. It might be considered instead as a memorial tribute, the distinguished financier died just before the book was published. The volume consists of numerous tributes showing the extent of Mr. Dapples' activities and the esteem in which he was held by his business and professional associates. The bulk of the volume, however, consists of scientific and medical papers contributed by French, German, Italian, Belgian, Swiss, English, Spanish, Netherlands and American investigators. Twenty-four papers from medical institutions, including reviews, case reports, laboratory and clinical studies, and fifteen papers from the different Nestlé laboratories are provided. The book is a fitting tribute to the man and to the great commercial organization whose destiny through many troublous years he successfully guided.

Lectures on the Epidemiology and Control of Syphilis, Tuberculosis and Whooping Cough and Other Aspects of Infectious Disease. By Thorvald Madsen, M.D., Director of the State Serum Institute of Denmark, Copenhagen. The Abraham Flexner Lectures Series Number Five. Published for Vanderbilt University. Cloth. Price \$3. Pp. 216 with illustrations. Baltimore: Williams & Wilkins Company, 1937.

The Abraham Flexner lectureship was established in 1927 at the Vanderbilt University School of Medicine by Mr. Bernard Flexner of New York. The income is used to secure a lecturer at intervals of two years, some eminent physician or scientist who is enabled by the terms of the gift not only to deliver a course of lectures but also to become a member of the medical faculty for a period of two months. The fifth and most recent lecturer in this series was Dr. Thorvald Madsen, who is director of the State Serum Institute of Denmark, Copenhagen, and chairman of the Health Committee of the League of Nations.

The five formal lectures delivered by him are now republished in book form to reach, it is hoped, a wider audience. The first is on the control of venereal disease in Denmark with special reference to syphilis, the second on the mechanism of bacterial infection, the third on tuberculosis in Denmark, the fourth on the influence of seasons on infection and the fifth on whooping cough. In each of these fields Denmark, and especially the investigators connected with Madsen's Serum Institute, have contributed pioneer investigations. Each lecture forms in itself a brief but scholarly treatise on the subject, and it would seem that no one who purports to keep an authoritative stand in any one of these fields can afford not to avail himself of the advantages and pleasure attendant on reading them.

Medicine Essentials for Practitioners and Students By G E Beaumont M A D M F R C P Physician to the Middlesex Hospital Third edition Cloth Price 21s Pp 780 with 74 illustrations London J & A Churchill Ltd 1937

For this edition the articles on several subjects, including pneumonitis, arachnoiditis, Niemann-Pick disease and barbiturate poisoning, have been rewritten. Several therapeutic additions have been made, including the use of prontosil, congo red, benzedrine and gold salts. Many other sections have been altered or revised. The book does not include sections on psychologic or dermatologic medicine, but even with those omissions the 700 odd pages are scarcely enough for adequate discussions of the remaining diseases—in fact, some sections are scarcely more than catalogues. The book suffers from the obvious necessity of discussing many diseases in limited space, and much essential information about many diseases has not been included. To beginning medical students, however, whose necessities require only the more prominent features of a large number of conditions, it may be useful. It seems doubtful whether it will replace in this country any of the excellent medical textbooks of indigenous origin.

A Dissertation on Acute Pericarditis By Oliver W Holmes Boards Price \$7.50 Pp 39 Boston Welch Bibliophilic Society 1937

The Welch Bibliophilic Society here makes available an essay by Oliver Wendell Holmes, written in three days as a thesis in connection with the receipt of the M D degree from Harvard in 1836. It is published without any correction of spelling, punctuation or other editing. The essay was not previously published and has been unnoticed in the archives of the Boston Medical Library until the present time. It is a model for a medical essay revealing in spots the humor of its distinguished author. Particularly witty was the selection as the opening quotation of the following: "The heart is deceitful above all things"—Jeremiah.

Microbiology in the Preservation of Animal Tissues By R B Haines B Sc Ph D Department of Scientific and Industrial Research Food Investigation Special Report No 45 Paper Price 65 cents Pp 85 with 20 illustrations New York British Library of Information London His Majesty's Stationery Office 1937

This little brochure outlines under three headings the problems connected with the preservation of meat. The first deals with how bacteria gain access to tissues. The second is concerned with some aspects of the physiology and biochemistry of bacteria and of the tissues of the host. The third part takes up the control of infection and the growth of bacteria, fungi and yeasts. There is an appendix containing a description of methods and apparatus for investigations on the preservation of meat. There is a bibliography containing 261 references. The author points out that successful storage of animal tissues is primarily an exercise in applied microbiology.

The Essentials of Pharmacology Materia Medica and Therapeutics for Medical Students By D M Macdonald M D F R C P E Cloth Price 7s 6d Pp 279 London Henry Kimpton 1938

This small book is intended to be a prescriber's handbook to enable him to conform with the British pharmacopoeia. It may also serve as a student's textbook, most especially for the purpose of brief review. A feature of particular interest in connection with each of the more important drugs is the item of 'prescribing note,' which suggests suitable methods of administration and of disguise. As is characteristic of our British confreres the old system of weights and measures is employed exclusively and the attempt is made throughout to inculcate prescription writing in Latin.

Miscellany

THERAPEUTICS AND PROPHYLAXIS OF MALARIA

Conclusions of Malaria Commission of the League of Nations

In 1935 the Malaria Commission of the League of Nations arranged for experiments to be made on the treatment and prophylaxis of malaria with synthetic drugs and with quinine so as to compare their efficacy. These experiments were conducted according to a plan which had been prepared beforehand. They covered 12,288 subjects and were carried out in Algeria, Italy, the Federated Malay States, Rumania and the Union of Socialist Soviet Republics under the direction of Prof Edmond Sergeant, Professor Bastianelli, Dr Neave Kingsbury, Professor Ciuca and Professor Sergueff, respectively.

The commission has drawn up the text of its fourth general report on the basis of lessons to be learned from these experiments. It represents the unanimous views of the commission and will shortly appear in the Bulletin of the Health Organization. The annexes will include an account of the experiments, a bibliographic review and the text of the observations made by the members of the Malaria Commission.

Following are the conclusions of the report.

ACTION OF QUININE AND OF SYNTHETIC PRODUCTS ON THE MANIFESTATIONS OF MALARIAL INFECTION

Quinine—A minimum daily dose of 0.5 Gm of quinine hydrochloride sometimes suffices to cause a temporary disappearance of the trophozoites of *Plasmodium vivax*, but a mean daily dosage of 1 Gm for from five to seven days is often necessary to cause the trophozoites to disappear (on an average on the third day) and not to make their reappearance in the peripheral blood until after a latent period of varying length, in the course of the first relapse. In quartan (*P. malariae*) the same effects are usually obtained. In infections with *P. falciparum* the average effective daily dose should be fixed at about 1.3 Gm to produce analogous results. In some countries it is necessary to use 2 Gm to obtain a rapid effect on the clinical attack and on the parasites. With the usual dose of 1 Gm the trophozoites generally disappear one day later, on the average, than in the case of *P. vivax*, sometimes their resistance continues even longer.

Quinine, in the doses indicated, exercises its parasitocidal activities on the young forms of *P. vivax* and *P. malariae* capable of producing gametocytes and also on fully developed gametocytes. On the fully developed gametocytes of *P. falciparum* quinine has only a slight action, but it also impedes the formation of the pregametocytes of this species. It may thus be regarded as directly schizonticidal and indirectly gametocidal in the case of *P. falciparum*.

On acute clinical symptoms of primary infection quinine, in the indicated doses, has a definite action from the third day onward (second paroxysms of fever) in benign tertian, its action is less reliable or less rapid, according to the strain or *P. falciparum* concerned on attacks of malignant tertian, which often continue until the fifth dose (third or fourth paroxysm).

On frequency of relapses in general, quinine has a marked effect which is, however, influenced by individual factors and by the strain of parasite. The treatment of primary *P. vivax* or *P. malariae* infections with quinine in the usual doses (1 Gm daily) is followed by relapses in a proportion of individuals which may be as high as 50 per cent.

Action of quinine on splenomegaly, when suitable treatment is applied in each attack, has proved of real efficacy in endemic regions, especially among children. It is but transient, however, if the community concerned is subject to a high proportion of relapses or is exposed to frequent reinfections.

Quinine treatment with the usual doses does not affect the patient's general condition adversely and generally has no depressive or toxic effect in the period of administration is limited to the strictly necessary number of days. In such a case there is no good reason for thinking that this treatment hinders the processes of immunization but ill effects may occur when treatment is unnecessarily protracted.

Atabrine—In daily doses of 0.3 Gm (for adults) atabrine has a slightly more rapid action on *P. vivax* trophozoites than quinine in the usual dose of 1 Gm. The trophozoites disappear on an average after the third dose, and in some cases even after the second. This parasitocidal action appears to continue for a longer period in that the phase of latency of the disease (absence of clinical symptoms) is established more certainly and lasts longer after the end of treatment with atabrine than with quinine. On the trophozoites of *P. malariae*, the action of atabrine is of the same nature. On the trophozoites of *P. falciparum* atabrine is equally in advance of quinine in certain cases, but the differences between the strains of parasites prevent the drawing of uniform conclusions. The trophozoites of *P. falciparum* disappear from the peripheral blood after the fourth dose of atabrine in 90 per cent of cases.

Action of atabrine on the gametocytes is of a similar nature to that of quinine. It has no effect, from the point of view of devitalization, on the gametocytes of *P. falciparum*. But the action on gametocytes already present in the blood is perhaps slightly more marked than that of quinine, particularly as regards the gametocytes of *P. vivax* and *P. malariae*.

Action on clinical symptoms of an acute attack is marked, both in benign tertian and in malignant tertian. In some endemic regions, where there may be special strains of *P. falciparum*, the therapeutic action of atabrine is more energetic on malignant tertian than on benign tertian but, in other cases, the contrary seems true. This is why some practitioners and malarialogists in tropical countries prefer to use quinine during the first days of the acute attack and to continue with atabrine thereafter. In benign tertian the fever nearly always falls after the first three therapeutic doses of atabrine—that is, by the second attack. In malignant tertian the fever falls almost invariably by the third attack.

Action of atabrine on relapses is slightly more effective than that of quinine, especially in the case of benign tertian and of certain strains of malignant tertian.

The spleen rate in communities treated with atabrine seems to decrease more slowly than in communities treated with quinine, but the effects of the drug continue to be felt for a longer time during the observation period after the end of the treatment, the decrease in the percentage of enlarged spleens continues longer, and the return of the splenic index figures to their former high level occurs a little later.

Action of atabrine on the general condition of patients seems to be determined by factors which, after this form of treatment, are still not entirely known, that is, by the action of the drug on the organic defenses in general and on the processes of immunization. The yellow coloration of the skin produced by atabrine is a disadvantage, especially during prolonged prophylactic treatments.

Plasmochin—The action of plasmochin on the trophozoites of *P. falciparum* is almost nil. It acts to some extent on the trophozoites of *P. vivax* and especially on those of *P. malariae*. With small nontoxic doses of plasmochin associated with the usual doses of quinine or atabrine, better results are sometimes obtained on the trophozoites of *P. vivax* and even of *P. falciparum*.

Plasmochin acts on gametocytes of the three species, but especially on those of *P. falciparum*, which are practically unaffected either by quinine or by atabrine. In minimum doses of 0.02 Gm, plasmochin devitalizes the gametocytes of *P. falciparum* and at the same time diminishes their numbers.

There is no advantage in using plasmochin alone for the treatment of the clinical symptoms of an acute attack in any of the forms of malarial infection.

Plasmochin has a definite effect on the frequency of relapses of benign tertian or quartan. In association with quinine or atabrine, or administered after either of these two drugs, it is to a marked degree effective in preventing relapses in benign tertian (except perhaps in the case of a few particular strains) and quartan, and appears similarly to reduce the frequency of malignant tertian relapses.

We do not possess sufficient data to assess the action of plasmochin alone, used either therapeutically or prophylactically, on the state of the spleen in malarial communities for it is nearly always administered together with other drugs.

The small doses of plasmochin (0.02 Gm, for example) are being used seem to have no seriously depressing effect on the general state of the patient. That the prolonged use of plasmochin may exert some influence on the formation of hemoglobin must not be overlooked.

Quinine-Atabrine, Quinine-Plasmochin and Atabrine-Plasmochin Combinations—The few experimental observations that have been published give no indication that there is any advantage in combining quinine and atabrine for purposes of treatment.¹ Further clinical research is required to determine the effects of these two drugs when administered one after the other (usually quinine first and atabrine afterward) in the treatment of acute attacks of certain kinds of infection, especially *P. falciparum*.

The combined use of quinine with plasmochin produces less frequent and less intense toxic symptoms than that of atabrine with plasmochin. The simultaneous use of quinine and plasmochin (or example, up to 0.02 or even 0.03 Gm of plasmochin daily for short treatments) therefore does not involve any particular contraindications. Certain authors recommend however that, whenever possible, the two drugs be administered consecutively. For the treatment of adult groups under observation there is, however, no serious disadvantage to be feared from the simultaneous use of quinine and plasmochin, which moreover shortens the duration of treatment.

The association of quinine with plasmochin represents one of the most efficacious methods of treating benign tertian and quartan malaria. Treatment with average doses (from 1 to 1.3 Gm) of quinine plus plasmochin (even only from 0.02 to 0.03 Gm twice a week) greatly reduces (perhaps more than any other method) the number of relapses in benign tertian (except, as already indicated, in the case of certain strains) and in some cases also in malignant tertian.

The simultaneous administration of atabrine and plasmochin appears to aggravate the toxicity of each. It should in any case not be adopted without medical supervision. Consecutive treatment with atabrine first and then with plasmochin in suitable doses (0.3 Gm of atabrine daily for five or seven days followed by 0.02 Gm of plasmochin daily for five days) has no appreciable influence either in reducing the proportion of trophozoites in the blood or on the clinical manifestation. Like the quinine plus plasmochin treatment, this method has the advantage of decreasing and devitalizing the gametocytes, especially those of *P. falciparum*. Moreover, it diminishes the number of relapses, both in malignant tertian and, more especially, in benign tertian and quartan.

PRACTICAL SUGGESTIONS FOR TREATMENT AND PROPHYLAXIS

Without presuming to lay down hard and fast rules, the commission believes that it is in a position to give certain indications. Account should, however, first be taken of the following points, on which reservations have been made in the previous pages, with respect not only to the individual treatment of patients but generally also to the application of any therapeutic procedure: (1) the varying reactions of the different parasite strains of the same species and of patients to the drugs, (2) the special indications applicable to the parenteral administration of drugs, (3) the drawbacks of the synthetic products (yellow coloration of the skin by atabrine, toxicity of plasmochin).

Individual Treatment of Patients—It is always desirable that the doctor should be in a position to diagnose malaria and to determine the species of parasite concerned by a microscopic examination of the blood.

In ordinary cases of *P. vivax* (benign tertian) infection it is almost immaterial whether quinine or atabrine is employed for treatment of the attack. Plasmochin associated with quinine or atabrine or administered after these drugs has no appreciably useful effect on the attacks but seems to reduce the frequency of subsequent relapses.

The association of plasmochin with quinine or its administration after atabrine, is useful in *P. falciparum* infections on account of its action on gametocytes and relapses.

¹ Professor Podhain in a private communication states that he has recently obtained beneficial effects by this method.

Treatment in the Field—Atabrine, when used for collective treatment in daily doses of 0.3 Gm (for adults) for from five to seven days, acts in the same way as quinine in daily doses of from 1 to 1.3 Gm for from five to seven days or more. There is no reason save financial considerations why either quinine or atabrine should be preferred. The manner in which collective treatment is conducted will depend on the intensity of the endemicity, which is itself the resultant of a series of factors: the incidence of malignant tertian infection (*P. falciparum*), the virulence of the strains, the sensitiveness of the strains to the various drugs and the susceptibility of various population groups.

Collective treatment with quinine or atabrine may usefully be accompanied or followed by plasmochin treatment, to diminish the number of gametocytes and the risk of relapses.

The choice of the basic drug for collective treatment should be left to the public administrations or malariologic organizations that undertake or control such treatment and will be guided by local and economic considerations as well as by the preferences of the medical profession and of the population. It should be remembered that the choice of drug, as well as dosage and duration of therapeutic administration, should, so far as possible, be directed toward the achievement of the real aim of mass treatment. This aim is to secure the largest number of complete cures in case of malaria and to reduce to a minimum the risk of anopheline infection, either by direct action on the gametocytes or by indirect action on the parasites generally, thereby effecting an eventual reduction in the number of carriers of sexual forms (gametocyte therapy). It would therefore be wise not to rely on plasmochin alone for this second purpose. These considerations also apply to the choice of the basic drug and the manner of its administration to the community either directly associated with or followed by plasmochin.

There are, however, large malarial areas, especially in the tropics, where such mass treatment is impossible of practical application for various reasons, often financial. Under such conditions it is desirable to provide adequate and easily available treatment for the clinical manifestations of the disease, so that the morbidity, the mortality and the physical incapacitation of the afflicted persons are diminished. Such treatment has very often to be placed in the hands of laymen for distribution, and little or no direct medical supervision is possible. In these circumstances, the cinchona alkaloids appear to be the more suitable drugs.

Mass Drug Prophylaxis—This has a twofold purpose: (1) to protect the population undergoing prophylactic treatment from the clinical manifestations of endemic malaria, in order that its working capacity and comparative standard of health may be safeguarded without injury to its preimmunization, even in areas in which it is exposed to repeated reinfection, (2) to reduce in due course, the sources from which the local mosquitoes may be infected.

No prophylactic method, unless applied to disciplined communities under stringent supervision, is capable as yet of attaining these two objects. Special stress should be laid on the desirability and the difficulty of promoting the immunization process in the population, which depends on the degree of tolerance to infection and on repeated reinfection. At the same time one wishes to avoid the risks attendant on the presence and persistence of such latent infections in the community.

Experience has shown, at all events, that useful results can be obtained with daily doses of quinine (0.4 Gm) administered during the whole of the malaria transmission season and even for a few weeks longer. This is also true of biweekly doses of atabrine (from 0.2 to 0.4 Gm a week) administered in certain conditions. With the latter method (biweekly atabrine), which has given encouraging results further trials would be desirable. The daily dose of 0.05 Gm of atabrine recommended for prophylactic purposes has proved inadequate. The harmlessness of quinine makes it a suitable drug for administration by subordinate personnel without constant medical supervision, whereas such supervision is essential in the case of atabrine.

Plasmochin should not be distributed for prophylactic treatment otherwise than under direct medical control. Its use in mass prophylaxis would be justifiable only if administered to a disciplined population which should be kept under constant

medical care. It is useful more especially for the purpose of ultimately reducing the number of gametocyte carriers and arresting the transmission of infection to the anopheles. Plasmochin is certainly the gametocidal agent *par excellence* especially where *P. falciparum* is concerned. But both quinine and atabrine also exercise in the latter case a gametocidal action by destroying the sexual forms in process of development.

The real efficiency of such methods in the field is, moreover, largely dependent on a highly important epidemiologic factor, namely, the children. The proportion of gametocyte carriers is much higher among children than among adults, given the same environmental conditions (village, house, family) in respect of endemicity and anophelism. Children on the other hand, are more difficult to subject to regular treatment, and finally the doses and form of administration of atabrine and plasmochin to children cannot be regarded as finally settled.

Drug Eradication—Experience has so far shown that the eradication of malaria from a locality by the curative and prophylactic treatment with the drugs at present available is practically impossible. It is impossible to reach in sufficient time, all the inhabitants of an area or even of a small village. Moreover, while curative and prophylactic treatment may greatly diminish the morbidity, it cannot suppress the parasites in all the carriers.

COMMENT

In this report the commission has not considered the question of expenditure entailed by treatment and prophylaxis campaigns, which depends on the price of drugs and the cost of the staff. It would, however, emphasize the great importance of this problem in connection with the choice of drugs to be used for curative or prophylactic mass treatment.

Among those drugs, quinine still ranks first in current practice by reason of its clinical effectiveness and almost complete absence of toxicity, coupled with the widespread knowledge of its use and dosage. As regards the synthetic products, the commission hopes that it has discharged the duty which devolved on it by giving an account of the present state of our knowledge regarding the possible use of atabrine and plasmochin. In certain circumstances as has been shown, these drugs—representing a notable scientific advance—possess a very special value.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Arteriosclerosis, Trauma and Cerebral Hemorrhage—An automobile backed into Heath a man of 63, bruising his arms. There was no fracture or severe lacerations. He died fifty-six days thereafter from a cerebral hemorrhage. Attributing the death to the accident, the widow brought suit against the driver of the car and its owner. From a judgment for the plaintiff the defendants appealed to the court of appeals of Tennessee, middle section.

There was evidence that Heath had had arteriosclerosis for a number of years and that a few months prior to the accident his systolic blood pressure was from 150 to 160. At the trial, the undisputed medical testimony was that the cause of a cerebral hemorrhage is high blood pressure acting on blood vessels weakened by disease and that such degeneration of the blood vessels is a progressive disease requiring years or time to weaken the blood vessels to the danger point. Arteriosclerosis results from a variety of causes such as senility, overeating, excessive use of tobacco or alcohol and certain diseases of the blood. Medical witnesses for the defendants testified that if by any possibility a trauma could cause a cerebral hemorrhage it would necessarily occur immediately after the injury, not several weeks later. A physician who testified for the plaintiff concurred in this view, testifying that it would be kind or hard to figure how a bruise on the arm could cause apoplexy two months later. While there was some evidence that an injury such as Heath suffered might temporarily,

increase the blood pressure, there was no evidence that, as a matter of fact, his blood pressure was higher at any time after the injury than before.

In view of the variety of causes of arteriosclerosis and high blood pressure, the progressive nature of those diseases and the absence of evidence excluding other causes, the finding by the jury that the cerebral hemorrhage suffered by Heath was caused by the injury inflicted rested, in the opinion of the court, on speculation. The court of appeals therefore reversed the judgment of the trial court, set aside the verdict of the jury, and dismissed the plaintiff's suit—*Willis v Heath* (Tenn.), 107 S W (2d) 228.

Evidence Testimony of Physician Based on Medical History as Related by Examinee Inadmissible—The opinion of a physician, says the Supreme Court of Minnesota, as to a person's condition, based wholly or in part on the history of the case as told to him by that person, is inadmissible in evidence where the physical examination made by the physician is made for the purpose of qualifying the physician to testify as a medical expert. The circumstances under which the descriptive statements of a sick or injured person as to the symptoms and effects of his malady and the opinion of the expert witnesses based thereon are admissible in evidence were stated in *Sund v Chicago, R I & P Ry Co*, 164 Minn 24, 204 N W 628, as follows:

First they must have been made to a medical attendant for the purpose of medical treatment. Second they must relate to existing pain or other symptoms from which the patient is suffering at the time and must not relate to past transactions or symptoms however closely related to the present sickness. Third such statements are only admissible when the medical attendant is called upon to give an expert opinion based in part upon them.

The danger of admitting such testimony is apparent. When a physician is consulted for the purpose of treatment, it may be assumed safely that the patient will tell the truth to the physician since he is interested primarily in being cured. However, when a person goes to a physician for the purpose of qualifying the latter to testify, the natural tendency and inducement would be to the contrary—*Preveden v Metropolitan Life Ins Co* (Minn.), 274 N W 685.

Workmen's Compensation Acts Employer's Liability for Hospital Expenses in Excess of Statutory Limit—Finch was injured in the course of his employment. An official of the defendant company, the employer, took him to the plaintiff hospital and instructed the superintendent to admit the workman and to procure a named physician to attend him. Later the employer refused to pay the hospital bill, and the hospital sued the employer. The court of appeals of Tennessee affirmed a judgment in favor of the hospital entered by the trial court, and the employer petitioned the Supreme Court of Tennessee for certiorari.

The employer contended that, since it was operating under the Tennessee workmen's compensation act and since the hospital knew that the workman was its employee, the extent of its liability was \$100, the maximum amount specified in the act that an injured workman can recover from his employer for hospital services. Compensation acts, answered the court, determine the rights of persons to whom such acts are applicable, that is, employers and employees, they do not reach contracts between physicians or hospitals and employers. While the court doubted that there was any express contract between the hospital and the employer in the present case, the court did think there was an implied contract. At common law, when a person secures services to be rendered, whether rendered to himself or to another, there is an implied contract to pay for such services. For reasons of humanity an exception is made generally in favor of a person calling a physician for another. Otherwise a neighbor or stranger might hesitate to call a physician to attend a stricken man unable to make such call himself. This exception, however, does not apply to a person under a legal obligation to supply medical services to another, as was the employer in this case.

The Supreme Court, therefore, affirmed the judgment of the trial court in favor of the hospital—*Weakley County Hospital v Kentucky-Tennessee Light & Power Co* (Tenn.) 107 S W (2d) 226.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Effect of Diuretics on Capacity of Lungs—Alsever and Levine present evidence concerning the value of diuretics in improving the respiratory function in patients with cardiac failure. Nine cardiac patients suffering from breathlessness in whom there was no evidence of peripheral edema or in whom the edema was only moderate in degree, were selected. In most instances the diuretic used was 1 or 2 cc of mercupurin (the sodium salt of trimethylclopentane-dicarboxylic acid-methoxy mercury-allylamide-theophylline) given intravenously. In some cases a similar amount of salyrgan or a mercupurin suppository was given. The specific effect of the diuresis on the respiratory mechanism was judged by measuring the vital capacity of the lungs just before the diuretic was injected and twenty-four hours later. Definite improvement in the respiratory function took place in every instance. There were eight patients in whom twelve readings were made before and after a diuresis. The average increase in vital capacity was 290 cc. The smallest increase was 125 cc and the largest was 600 cc. The diuretic effect of the injections was manifested by the prompt and decided increase in the urinary output and the loss of weight which took place during the twenty-four hour period. The results illustrate the benefit that may be obtained from diuretics in the distressing symptom of breathlessness entirely apart from the well known effect on edema. It follows that if a diuretic extracts fluid from the engorged capillary bed of the lungs both the amount of the remaining air spaces will increase and the capacity for oxygenation of the blood will improve.

Calcium in Blood Serum, Calcium Balance and Metabolism During Pregnancy—During the last four years, Pyle and his co-workers have observed the three day test samples of mineral balances during pregnancy. The subjects were to weigh their food and to eat the same kind and quantity for three successive days. On the third day the food was sampled and collections of the twenty-four hour excretion of urine and the feces from the corresponding twenty-four hour ingestion were made. On the morning of the fourth day, blood was drawn for serum calcium immediately after the basal metabolic rate was determined. The level of calcium in the food has little effect on the amount of calcium carried in the serum. The fraction of calcium possibly available to the fetus is affected by the oxygen consumption of the mother. This fraction also contains calcium filtered from the maternal system by the kidney. Measuring the serum calcium level alone shows little regarding the ingestion level or the level of calcium in the urine during pregnancy. Serum calcium determinations showed less about maternal weight gain during pregnancy than urinary, food or fecal calcium did. Urinary calcium showed more about oxygen consumption than the level in serum, food and feces did. The fecal level was the most sensitive indicator of weight gain during pregnancy for these subjects, the urinary level being the most sensitive indicator of oxygen consumption.

Results with Visscher-Bowman Pregnancy Test—Dunn and Northway tested 395 urines by the Visscher-Bowman method for the determination of pregnancy. Correct reactions were obtained in 84.8 per cent of 250 known pregnancies, 87.6 per cent of sixty-five suspected pregnancies and 54.8 per cent of sixty-two nonpregnancies. Urines of low specific gravity or containing unusual amounts of catabolic reducing agents tend to give false reactions. The test in its present form is subject to too high a percentage of error to replace the Friedman and Aschheim-Zondek tests.

Gonadotropic Substance for Diagnosis of Pregnancy—Gersh carried out the gonadotropic substance cutaneous test for pregnancy on 113 persons. Fifty were normal men and non-pregnant women, forty-eight were known cases of pregnancy of a duration of two or more months and fifteen were from one to nine days post partum. The results of the reaction show the test to be entirely unreliable.

Study of the "Cold Test" in Normal and in Toxemic Pregnancy—Reid and Teel performed the "cold test" at intervals of from four to six weeks throughout pregnancy and the puerperium on thirty-four normal patients. The results on normal and toxemic pregnant patients fail to support the suggestion that the test might reveal impending toxemia. Nor did they find the test of practical value in the differential diagnosis of pregnancy toxemias. The marked variations in response in

different patients of each clinical group, as well as considerable differences in the response of the same patient at different times, would exclude any value for the test in differential diagnosis for any individual case

Air Myelography—Young and Scott have used subarachnoid injections of air at the Temple University Hospital since January 1936 in any patient suspected of having a tumor of the spinal cord or any other space-taking lesion of the spinal canal. Their studies emphasize the accuracy of the method, in each of their thirteen cases the exact level of the lesion, demonstrated by air myelography, was verified by laminectomy. The efficacy and simplicity of the procedure cannot be doubted when a complete block exists. Practically this amounts to a lumbar puncture, with injection of a few cubic centimeters of air, and roentgenograms of the spine taken with the patient in the sitting posture. The trapped air is easily visualized on the roentgenogram and the level is thus established. The lumbocaudal sac is easily filled with air and is clearly delineated by it. Nucleus pulposus (or cartilaginous disk) herniations may be discovered if this is done, so there is no reason for the use of iodized oil for this condition unless air studies are negative. The diagnosis of a partial block entails no more work than does a complete one if sufficient air is trapped below the block to see it, but if the air passes into the cranium it is still possible to visualize the lesion at another sitting by replacing spinal fluid with air through cisternal puncture with the patient in the Trendelenburg position. There is practically no pain or untoward effect when from 3 to 6 cc of air is used. When large amounts are used to outline the lumbocaudal sac or the entire spinal canal the patient should be kept in the Trendelenburg position (from 20 to 30 degrees) for six hours and flat on the back for twelve hours and should be gradually elevated to the erect position over a period of forty-eight hours. If this procedure is followed, little headache results. It is not essential that roentgenograms be taken immediately after the injection of air if the patient is kept in the Trendelenburg position, as air has been found in the subarachnoid space below a complete block for as long as one week after injection.

Roentgenologic Aspects of Mastoiditis—Schillinger believes that if prophylaxis against mastoiditis is to be practiced it must be applied to every case of suppurative otitis media and that the only available and effective prophylactic agent is roentgen irradiation. In small doses it has a wide margin of safety is prompt in its action and produces no bad effects. An exposure dose of from 20 to 50 roentgens administered on about the

seventh day of suppuration and repeated at intervals of two or three days for a total of three or four exposures, will materially reduce the incidence of mastoiditis.

Effects of Irradiation on Normal Blood Cells—To determine the effect of therapeutic irradiation on the erythrocytes and hemoglobin of the circulating blood as revealed by the red cell count and hemoglobin determination and the effect of irradiation on the leukocytes as determined by the white cell count, Kornblum and his associates performed such studies before and after irradiation on 100 unselected patients with benign and malignant conditions, the latter predominating. Roentgen and radium irradiation as applied therapeutically has no significant effect on the red cell count or the hemoglobin content of the blood. Anemia alone is not a contraindication to radiation therapy. Therapeutic irradiation tends to lower the leukocyte count. The greatest decrease occurs in the lymphocytes and then in the neutrophils, with the monocytes and eosinophils being the least affected. There was no apparent relationship between the effect on the leukocytes and the part of the body treated, the amount of irradiation and the period of time during which the patient was irradiated. About five weeks is required after irradiation for the count of the various leukocytes to return to the preirradiation level. A count which does not recover in a period of eight weeks is suggestive of an unfavorable prognosis. Daily intramuscular injections of 2 cc of liver extract did not prevent the depressing effect of irradiation on the leukocyte count. Irradiation leukopenia does not prevent an increase in the number of leukocytes when infection occurs, but this increase is not as great as occurs in nonirradiated individuals. Intravenous injection of typhoid vaccine, which normally causes a sharp rise in the leukocyte count, produced no significant effect in patients receiving or immediately following a series of radiation treatments. Several months after the cessation of therapy a characteristic response was obtained. Injections of liver extract or typhoid vaccine afford a means of determining whether the blood of an irradiated patient has sufficiently recovered to permit a second series of treatments. It seems inadvisable to permit the neutrophils to drop below 1,000 and the lymphocytes below 250 cells per cubic millimeter of blood. From a practical point of view the effects of irradiation on normal blood, as determined by the blood count, are of little clinical significance.

Surgical Treatment of Chronic Pulmonary Suppuration—Lanman states that radical surgical procedures for bronchiectasis have a low mortality rate in children. There have been seven lobectomies for bronchiectasis with no operative deaths.

and three total pneumonectomies for bronchiectasis with one operative death. All the patients were less than 12 years of age. The youngest was 6 years old. All were submitted to a one stage operation. These patients have been observed for from three months to four years. Excluding the one operative death and one other patient who died of brain abscess four months after lobectomy, all the patients are improved or doing well. The foundation of chronic pulmonary suppuration in adults is often laid during childhood. Prevention is better than its treatment. The group of cases that has as its etiologic agent a foreign body is the most obvious type for which preventive measures are useful. It is probable that an earlier and more radical treatment of "chronic unresolved pneumonia" or "chronic pneumonitis," associated with a fibrinous pleurisy but without appreciable free pleural pus, may prevent the establishment of a bronchiectasis or even gangrene. Complete and bacteriologic studies are much to be desired. Such studies may give some reliable information on the etiology and prognosis of certain types of bronchiectasis in children.

Primary Bone Tumors in Children—Coley and Peterson point out that the early recognition of primary tumors of the bone in children lies in the field of pediatrics and of orthopedic surgery. There are obstacles to be overcome in arriving at a diagnosis. The first of these is the tendency to explain persistent pain in an extremity on the basis of a rheumatic or neuritic condition and to neglect to obtain early roentgenograms of the affected part. Pain not readily explainable on some other grounds should at once arouse suspicion of a primary sarcoma of the bone; and an immediate attempt should be made to establish the diagnosis beyond question. This calls for an early and thorough x-ray examination, to be repeated if inconclusive. Pain is the first and most important symptom, this may precede any visible swelling by weeks or even months. Unless definite signs of an acute infection are present, pain in an extremity in a healthy young person should lead one to suspect the presence of a bone sarcoma even before an external swelling makes it obvious. The acute onset and marked constitutional symptoms that accompany the pain in acute osteomyelitis in children serves to differentiate this condition from sarcoma. A small tumor that has been present without change for several years and is not associated with severe pain is probably benign. On the other hand, pain associated with a tumor of large size or rapid rate of growth points to a malignant process. Again, if the swelling appears promptly after a muscular bruise, grows rapidly at first and then reaches a quiescent state, it is quite probable that the condition may be one of myositis ossificans.

Plasmapheresis and Edema Formation—His plasmapheresis experiments on dogs prove to Kerkhof that the maintenance of the colloid osmotic pressure at the normal level by some inert colloid (acacia) is sufficient to stop any tendency to edema formation. Even when the protein levels were reduced to values far below the level at which edema usually appears in such an experiment when acacia is not given, edema did not develop. These experiments prove that the tendency to edema formation is a function of the colloid osmotic pressure of the plasma and would tend to show that one of the main functions of proteins in the plasma is the maintenance of a normal colloid osmotic pressure.

Ocular Manifestations of Endocrine Disturbance—Because of the facility of studying directly under *in vivo* conditions the living ectoderm, mesoderm and, to a lesser degree, endoderm, and because of the dual control system of the vagus and sympathetic nerves, Lemoine declares that the eye provides an excellent medium for the study of endocrine disturbances. The ophthalmologist should train himself to recognize the signs of endocrine malfunction. Before one attempts to attribute any ocular manifestation to an endocrine disturbance, other disease entities should be eliminated, because in the presence of any other disease one is not justified in making a definite diagnosis of endocrine disease. Glaucoma has frequently been mentioned as being of endocrine origin but it should not be expected to be the result of a single endocrine syndrome. Some cataracts have been placed in the category of endocrine disturbances by a number of authors and cataracts have been attributed to hypofunction of the pancreas, the parathyroids, the thyroid, the gonads and the adrenal cortex and to hyperfunction of both the anterior and the posterior lobe of the pituitary gland. The one observation frequently encountered in patients with cataract (both the congenital and the senile cortical type) is hypothyroidism and in a great number of these cases there is also an associated

hypogonadism On a physiologic basis, acquired myopia may possibly be due to endocrine disturbances, either hyperactivity of the adrenal cortex or the posterior lobe of the pituitary gland or hypoactivity of the anterior lobe of the pituitary gland, the adrenal medulla, the thyroid and the gonads. In keratoconus there probably is a relation to some endocrine dysfunction not yet fully understood. Uveitis has been reported in association with endocrine disturbance, but except when it was due to diabetes the symptoms in most of the cases were only suggestive of an endocrine dysfunction. Retinitis pigmentosa has been associated with dysfunction of most of the endocrine glands but on a physiologic basis it is not likely to be associated primarily with any gland but the pituitary or the adrenal.

Treatment of Tuberculous Laryngitis—Banyar applied cod liver oil topically in 126 cases of tuberculosis of the throat. Of these, ninety-one cases of laryngeal and six of pharyngeal tuberculosis were analyzed. Thirty-seven patients with laryngeal tuberculosis died, twenty-nine in less than two months. Pharyngeal and laryngeal ulcers showed rapid epithelization and healing. A favorable therapeutic response was seen in cases in which there was localized infiltration or vegetative granulation. Laryngeal tuberculosis with marked edema is rather resistant to this treatment. Of ninety-one patients with laryngeal tuberculosis whose treatment lasted from two months to one and a half years, twenty-four remained unimproved, forty-two improved subjectively and objectively and twenty-five were healed. In the majority of the cases in which healing occurred, it was established before the patient recovered from the pulmonary tuberculosis. The evidences of symptomatic relief, such as elimination of pain, dysphagia and irritation in the throat, diminution of the cough and easier expectoration were promptly noticeable. Restoration of the normal voice, better sleep and improvement in the patient's general well-being accompanied the objective manifestations of healing.

Relief of Neuritic Pain by Artificial Fever Therapy

—At the University of Nebraska Bennett and Cash have been using the hypertherm for the induction of artificial fever in a large variety of diseases. Up to Jan. 1, 1937, in twenty-six months, they have treated 581 patients, who received more than 2,650 fever treatments. Of these patients forty have under-

gone fever therapy in an attempt to obtain relief from neuritis, myalgic or radicular painful states. There were twenty cases of sciatic neuritis, six of brachial neuritis, five of toxic infectious polyneuritis and infective neuritis, three of herpes zoster, two of lymphocytic meningitis and four of miscellaneous arthritic states with secondary neuritis or neuralgia. All types of neuritic pain were relieved immediately, but pain recurred in some cases, especially in the secondary neuritis from compressive lesions. This form of heat therapy (from 103 to 104°F) is a distinct advance over all local forms of heat in relieving pain. Fever therapy is not recommended to replace other accepted forms of therapy in neuritis but only as an aid in the management. It probably hastens convalescence in the severe toxic infectious polyneuritic states. The physiologic mechanism of general fever induction effecting relief of neuritic pain is not well understood. Undoubtedly the enhanced blood flow at peripheral vasodilatation in the inflamed areas increases tissue oxidation and nutrition. Leukocytosis, phagocytosis and mobilization of immune bodies secondary to induced fever play a part in the absorption of rheumatic deposits, dilution of toxins and the healing of inflamed nerve tissues. The treatments do not interfere with any other indicated therapy and are practically without danger in experienced hands.

Encephalopathy and Anemia Due to Volatile Solvents

—The Parsons report the cases of two young men who worked in a shirt factory in constant contact with volatile solvents which were so concentrated in the air of the dipping room that they and the other workers in this room suffered

from burning and watering of the eyes, severe enough to produce conjunctival irritation. The solvents were used for stiffening the collars of shirts. The two patients also showed moderately severe symptoms of 1 Toxic encephalopathy, as evidenced by personality change, frequent dizzy and faint spells, tendency to sleepiness, loss of all interest in their normal amusements and activities after working hours, general hyper-tonicity of all skeletal muscles somewhat resembling the rigidity of recuperating tetanus cases, hyperactivity of all reflexes, transitory right ankle clonus, persistent dilation of pupils and sluggishness of reaction of pupils to light and in accommodation, and moderate ataxia and positive Romberg sign. 2 Anemia, which was moderately severe and associated with granulopenia. The toxin had its greatest destructive effect on the neutrophilic leukocytes which circulated in the blood stream, and the bone marrow was so overstimulated to activity in its failing effort to reproduce neutrophilic cells that it poured young forms, such as myelocytes and young neutrophils, into the blood stream. There was a moderate decrease in the number of red blood cells with a high color index. The picture was similar in some respects to that of benzene or radium poisoning. Whereas the weakness and dizziness might possibly have been caused by the anemia, this seems unlikely, especially since these symptoms were more pronounced in the second patient who had the less severe anemia. The continuance of these symptoms for a considerable time after the blood had reached normal levels in both cases also would suggest the assumption that they resulted mainly from a toxic effect on the central nervous system. Patient 1 showed gastrointestinal symptoms with some signs of acidosis, probably due to vomiting. Both men showed a loss of weight. Although there were no signs of renal irritation, the development of a consistent nocturia (twice nightly) in both cases indicated some disturbance in renal function. The fluid in the "dipping tank" contained ethylene glycol monomethyl ether and a substance containing 90 per cent ethyl alcohol, 44 per cent methyl alcohol, 47 per cent ethyl acetate and 09 per cent petroleum naphtha. Removal of the patients from exposure to the volatile toxic solvent together with treatment for their anemia, resulted in complete symptomatic and objective physical recovery from the poisonous effects on the central nervous system and the blood forming organs with apparently no permanent damage. Follow-up blood counts made eleven months after removal from contact showed continued persistence of neutrophil-lymphocyte relationship and high color index.

Health Hazards in Exposure to a Volatile Solvent—Greenburg and his associates performed clinical and hematologic studies on nineteen employees in the collar fusing department of a shirt factory in which ethylene glycol monomethyl ether was used in conjunction with denatured alcohol as a solvent for cellulose acetate. All the subjects had abnormal blood pictures. Clinically, however, they fell into three main groups: those with a negative clinical picture, those with abnormal neurologic changes on physical examinations but no symptoms and those with abnormal neurologic signs on physical examinations and symptoms of fatigue and drowsiness. Disturbances of erythropoiesis were found in nine cases. A general immaturity (shift to the left) of the neutrophilic granulocytes was found in every case. The blood platelets were fewer than normal in the majority of the cases and in several cases abnormal platelet forms were found. The blood picture as a whole is believed to be suggestive of a macrocytic anemia associated with a reduction in the platelets and a relatively large number of young granulocytes. The responsibility of ethylene glycol monomethyl ether for these changes is suggested. As a result of the present experience, the concentration of this substance in the air should be kept below 25 parts per million.

Health Hazards in Exposure to Acetone-Methanol—As a control for their previous investigation, Greenburg and his colleagues also studied nineteen workers exposed to the fumes of acetone and methanol in a collar fusing plant. Physical examinations revealed no abnormalities. Blood studies revealed no disturbances in hematopoiesis. Absorption of acetone was demonstrated by finding this substance in the urine of every worker. The concentration of solvents (25 parts per million of methyl alcohol and 40 of acetone) in the workroom atmosphere was apparently not high enough to cause pathologic changes.

Lung Volume After Thoracoplasty—Harter and his colleagues during the last two and a half years have combined the resection of the upper ribs with a mobilization of the apex, providing vertical as well as lateral collapse of the lung in the upper portion of the chest. An apparently more effective control of tuberculosis follows with less sacrifice of the uninvolved lung. Clinical impressions drawn from 179 patients who have had far-advanced tuberculosis arrested by thoracoplasty and from 121 of these patients who are now working are that the great majority of rehabilitated thoracoplasty patients do very well in respect to pulmonary function. Two observations have prevented the authors from becoming unduly alarmed. 1 Relatively few patients complain of dyspnea on exertion or show other effects of pulmonary deficiency. 2 A few patients who had symptoms such as tightness in the chest, wheezing or dyspnea on slight exertion have been relieved by selective thoracoplasty. The readjustment of the size of the thoracic cage to the size of the healthy lung, the relaxation of distorted pulmonary tissue, the dropping of the hilus and the return of the lower lobe and diaphragm to normal positions may increase the patient's ability to use the remaining uninvolved lung. A significant evaluation of the volume of the lung should be delayed for several months, preferably when the disease is arrested and the patient is ambulatory. Preoperative determinations of the volume of the lung were made on seventy-two consecutive patients with the method of Christie. Postoperative studies were made on thirty-two patients. The interval between the last operation and the determination varied from four to eighteen months. The tuberculosis was apparently arrested and all the patients were ambulatory or working. The postoperative status of the thirty-two patients was that sixteen were rehabilitated and sixteen became ambulatory. The preoperative vital capacity varied from 1090 to 4020 cc and the postoperative from 827 to 3465. The preoperative volume of the lung was

from 998 to 5,320 cc and the postoperative from 795 to 3,540. The ages of the patients ranged from 20 to 58 years. There were twelve men and twenty women.

Pulmonary and Circulatory Function After Thoracoplasty—Lambert and his associates observed eleven patients having pulmonary tuberculosis from the preoperative state through thoracoplasty. They selected three for detailed description. The first had had neither pneumothorax nor phrenicectomy, previous to thoracoplasty. The second had had a phrenicectomy two years before. The third had at the time of thoracoplasty a partial pneumothorax, also a benign tuberculous empyema in the pneumothorax cavity. The initial and final stages of each are compared. 1 In the first patient after operative collapse of the diseased upper part of the left lung, exertional dyspnea was practically the same as before operation. A decreased breathing capacity, due to the collapse of the wall of the chest, was compensated for by more efficient exchange of air in the remaining good lung. Ventilation during exercise was smaller, oxygen utilization of inspired air was greater and there was no accumulation of carbon dioxide in the arterial blood after exercise. 2 In the second patient there was a great reduction of lung volumes and breathing capacity. The response to exercise in the preoperative state showed high ventilation, poor oxygen utilization and low arterial oxygen saturation, indicating inadequate pulmonary function. Results of venous pressure and vital capacity measurements after intravenous infusion suggested some congestion in the pulmonary vascular bed. Functional studies in the postoperative state showed essentially the same abnormalities as in the preoperative state. Dyspnea postoperatively was somewhat increased. 3 In the last patient artificial pneumothorax had failed to collapse the diseased lung but had collapsed the nondiseased lower lobe. A benign tuberculous empyema had developed. Restriction in lung volumes and breathing capacity was marked. During exercise, ventilation was not abnormally large. After exercise there was arterial oxygen unsaturation, large lactic acid accumulation and rise in arterial carbon dioxide tension. Following operative collapse of the diseased lung, arterial oxygen saturation after exercise was normal. Breathing capacity was still much restricted, venous pressure after intravenous infusion was increased greatly. The lower part of the right lobe was then allowed to reexpand gradually when ventilation after exercise became normal, oxygen utilization was good, arterial oxygen saturation was normal and change in the level of carbon dioxide curve was small. Exercise was accomplished without dyspnea.

Relation of Ocular and Otolaryngologic Lesions to Chronic Prostatitis—Haven presents four cases to illustrate some of the clinical details in the relation between lesions of the eye, sinuses, tonsils and prostate. Case 1 illustrates that one negative prostatic smear does not prove the absence of

prostatic infection. In the first examination of the prostatic secretions there were only five pus cells per high power field. This was an instance of an ocular lesion occurring in the presence of multiple foci. The inflammation of the eyes disappeared after tonsillectomy but recurred and healed only after the prostatic infection was thoroughly treated. Case 2 is an example either of tonsillar infection being overlooked or neglected or of tonsillar infection developing since the last examination. It emphasizes the importance of rechecking the nose and throat for foci when a chronic pyogenic prostatitis is not responding well to treatment. In case 3 there was no history of gonorrhea, the prostatitis was probably of hematogenous origin in connection with an influenza and thrombophlebitis. The chronic sinusitis was a focus which retarded the improvement of the prostatic infection under local treatment. Case 4 is a clinical example of too vigorous prostatic massage precipitating an ocular lesion. The prostatic infection was favorably influenced by sulfanilamide by mouth, and a corneal ulcer in the left eye improved rapidly after the prostatic infection was brought under control. The corneal ulcer in the right eye was healed by nonspecific protein therapy and the elimination of infection in teeth and tonsils. The mechanism by which a focus of infection produces an endogenous ocular lesion may be due to the transfer of bacteria or of bacterial toxins. Recent experimental work indicates the possibility of an allergic phenomenon being involved.

Symptoms of Nonvenereal Prostatitis—Wesson points out that the incidence of extension of the gonococcus to the prostate is slight. There is commonly present an active non-specific prostatitis and seminal vesiculitis of true systemic origin or a quiescent infection of local origin, and this is activated by invasion of the urethra by the gonococcus. Acute prostatitis is generally due to urethral instrumentation, an acute nonspecific urethritis, cystitis and the like. Chronic prostatitis is a chronic pyogenic infection of the prostate, having its origin in direct extension from the urethra, or invasion through the blood stream or lymphatics. Whenever a state of chronic congestion continues for any length of time, the resistance of the prostate and seminal vesicles is lowered to such an extent that a non-specific infection is prone to develop. A patient with a pain in the lower part of the back or one in the groin that extends suprapubically toward the midline below the umbilicus or down into the scrotum, with a prostate and seminal vesicles that are nodular and indurated on palpation, whose prostatic secretion contains pus and dead spermatozoa and who complains of an exacerbation of the pain on massage has not a beginning hernia or "sacro iliac slip" but a prostatic backache. The epididymitis that frequently occurs spontaneously is due to an extension of the prostatic infection down the vas. Low back pain with a short period of disability is due to myofascitis, a prearthritic condition, while that of long duration is the result of hypertrophic arthritis of the spine. Attacks of gout are frequently aborted by prostatic massage, the symptoms being in the main due to the coexisting arthritis and not to the gout. In acute prostatitis there is usually urinary difficulty. In chronic prostatitis there are no pathognomonic symptoms of the bladder. Prostatitis usually causes no sexual disturbances, but it may be responsible for every phase of derangement from mild inaptitude to complete impotence. Because of the close relationship between the seminal vesicles, ureters and peritoneum, abdominal symptoms are not uncommon. Intestinal obstruction, alleged to be secondary to pressure of swollen seminal vesicles but probably really due to an adynamic ileus, has been reported. Ophthalmologists have found that iridocyclitis and retinitis are occasionally due solely to prostatitis, as such persist after the removal of infected foci in teeth, tonsils and sinuses but clear up with treatment of the prostate. An infected prostate may simulate lesions in distant parts of the body. Prostatic pain is relayed through the sympathetic system to the primary cells in the ganglions and then referred outward through the various connecting ramifications to the organs which these nerve cells supply, giving rise to symptoms not necessarily of pain but related to the function of the organ affected. The impulse of the pain arising in the prostate may reach the central nervous system along the thoracicolumbar sympathetic nerves, the afferent sympathetics form

ing synaptic junctions either in the spinal ganglions or in the anterior column of the spinal cord, to be relayed through the somatic or sympathetic efferent systems. The exact level of their entrance into the spinal cord is doubtful

Absorption of Dextrose from Small Intestine in Deficiency Disease—Groen studied the absorption of dextrose in three patients suffering from organic disease of the intestine associated with diarrhea (tuberculous enteritis, ulcerative colitis and nontropical sprue). In each case decreased absorption was demonstrated. Among ten patients with various dietary deficiency diseases, diminished absorption of dextrose was found before treatment in three cases of pernicious anemia and in one case of alcoholic polyneuritis with pellagra. Absorption of dextrose in these four cases returned to normal after treatment. The absorption of dextrose was found to be normal after treatment had been applied in one additional case of pernicious anemia and in two additional cases of alcoholic polyneuritis. However, there was a normal absorption of dextrose in two cases of scurvy before treatment. In cases in which the absorption of dextrose was diminished, the blood sugar showed a smaller rise during the absorption test than in control observations on normal subjects. The flat blood sugar tolerance curve often found in sprue and sometimes in pernicious anemia and certain other dietary deficiency states is attributable at least in part to a diminished absorptive power of the intestine. The decreased absorption of dextrose in deficiency disease is likely to be a specific effect due to a lack of some component or metabolic derivative of the vitamin B complex.

Extrascapular Apicolysis—Gale and Midelfart report sixty-five instances of thoracoplasty with extrascapular apicolysis (Semb) and eight revision operations. Since the procedure is rather recent, the complications were frequent in the earlier cases. These have been reduced greatly with an increasing experience, a more careful selection of cases and the proper timing of the operative stages. The percentage of cavity closures and sputum conversions has been gratifying. An increasing number of patients are already being discharged from the sanatoriums with the condition arrested. The group of revision operations is too small to evaluate except that the most serious complication to be encountered is the accidental opening of the tuberculous cavity. This is best treated by packing the wound wide open to ensure adequate drainage.

Radiotherapy in Eczema—Whitby states that all rays act by absorption, and the majority of the systems are reached directly or indirectly, ultraviolet rays have not the penetrating power of infra-red rays, but they stimulate the endocrine glands in particular, which in turn cause an acceleration of the calcium metabolism, which is so important in the progress of cutaneous treatments. Calcium can be given by other means but the results of ray application have more than justified their use, chiefly by their rapid action. Ultraviolet rays stimulate the central nervous system, giving the patient a feeling of well being, but the first and foremost effect aimed at is the relief of pruritus or even pain. Infra-red rays penetrate deeply and in so doing have an analgesic influence on the nerve endings with the result that the pruritus is kept under control. At the same time they absorb the exudate, thus improving the local blood supply and calcium metabolism. Secondary infections soon cease and the results are lasting. Filtered light is a useful adjuvant in this condition, the lamp used is the 1,000 watt carbon filament and the best screen is the red, which not only has sedative effects but also acts as an additional stimulant. There are a series of sound measures for combating cutaneous ailments, but a definite technic is impractical.

Chronic Regional Colitis—James reports a case of chronic nonspecific inflammation of an isolated part of the colon. The condition was established as a clinical and pathologic entity by Moschowitz and Wilensky in 1923. In most of the cases

described, the lesion has shown a predilection for the terminal portion of the ileum, but any part of the intestinal tract may be involved. The clinical features of the case presented are typical. Young adults are most commonly affected—men more than women—and the common symptoms are abdominal pain, loss of weight, low grade fever, anemia, diarrhea and a palpable mass in the abdomen. The etiology is unknown. No specific organism has been recovered from the feces, the affected intestinal wall or the lymph glands. Pathologically, the changes are those of a nonspecific granulomatous inflammation associated with ulceration of the mucosa and hyperplastic and exudative changes involving all the layers of the intestine. As the condition progresses, the exudative reaction is followed by fibroblastic transformation, with narrowing of the intestinal lumen. The presence of giant cells in histologic sections has not been responsible for a frequent diagnosis of hyperplastic tuberculosis, especially when the ileocecal region has been involved, but careful microscopic examination does not show the characteristics of tuberculosis. Giant cells are not an essential feature of the pathologic process. The complete absence of any healed or active tuberculosis elsewhere, together with negative tuberculous tests, is against the lesion being tuberculous. Chronic regional colitis or enteritis may in some respects simulate ulcerative colitis, but the diarrhea seldom approaches in severity that of this disease. In ulcerative colitis there is seldom a marked connective tissue reaction in the wall of the intestine, and a tumorous mass is seldom palpable in uncomplicated cases. Sigmoidoscopy usually shows characteristic changes. If the general condition is satisfactory, resection wide of the affected area is advisable to prevent recurrence at the site of anastomosis. When the general condition of the patient prohibits more radical measures a short circuiting operation should be performed, with removal of the involved segment at a later date if symptoms persist.

Acute Regional Ileitis—Maier discusses the evidence obtained in a case of acute regional ileitis that *Streptococcus viridans* is the bacterial agent involved. The isolation of this pathogenic organism from the blood stream was suggestive and, though the handling of the intestine at operation may have been responsible for its appearance in the circulation, the finding is no less valid on that account. *Streptococcus viridans* is capable of giving rise to a relatively low grade inflammation similar to that present in regional ileitis. Unfortunately the finding of this organism does not solve all the problems connected with the causation of the disease. If acute ileitis resembled most other acute inflammatory conditions in going on to complete resolution, it might be justifiable to regard it as septicemic in origin and its localization in the ileum as being determined by the large amount of lymphoid tissue there. On the other hand, it is probable that the disease usually runs a more chronic course, that an acute flare-up is incidental and is due either to an increased virulence of the organisms concerned or to localized venous thrombosis with some degree of hemorrhagic infarction. The great increase in the amount of fibrous tissue in the wall of the intestine, which was a feature of Jackman's acute cases, would bear this out. The disease therefore has some features in common with chronic ulcerative colitis and has been regarded by some as simply a localized form of this disease. Such a conception does not necessarily minimize the role of *Streptococcus viridans* as the main bacterial invader, but on the other hand, as in ulcerative colitis, it does postulate some additional factor to account for the susceptibility to the disease and its tendency to chronicity. There is general agreement that acute ileitis should be treated conservatively, as there is a tendency to spontaneous resolution. Laparotomy is, however, always necessary for diagnostic purposes. If the disease has extended beyond the intestinal wall and has caused marked infiltration of the mesentery, spontaneous recovery is less likely and either short circuiting or excision may be necessary. Many patients get well but whether they remain well indefinitely or by gradual stages acquire the chronic fibrostenotic form described by Crohn is not known.

Surgery of Pineal Organ—Wakeley states that the surgery of the pineal organ although yet in its infancy is advancing rapidly. The symptomatology tends to be more definite, there are usually severe intracranial pressure, headache, vomiting, papilledema, epileptiform fits and some paralysis of the cranial

nerves The eye signs are definite, with loss of pupillary reaction and failure of upward movement of the eyes Operations for the removal of pineal tumors have become standardized, and even if the complete removal cannot be undertaken, a post-operative course of high voltage roentgen therapy will complete the cure, as the majority of pineal tumors are radiosensitive There is no reason why the operative mortality should not be reduced to a low figure and the results become as good as those for the removal of a pituitary tumor The nine cases observed since 1919 are cited

Effect of Sulfanilamide on Blood Picture—Campbell estimated the activity of the bone marrow by enumeration of the reticulocytes and leukocytes in the peripheral blood of ten patients Whenever possible, observations were made daily or every second day for a definite period before the administration of sulfanilamide, during treatment and for a varying period after cessation of therapy The duration of the latter period depended on the return to or maintenance of normal levels and the length of stay of the patient in the hospital In addition to the ten cases nine others were observed in which less systematic blood examinations were made In four cases the reticulocyte level was above the normal 2 per cent before treatment was started which indicates that a mild reticulocytosis is not uncommon in the presence of sepsis In three of these cases no increase in the reticulocytes by more than 1.4 per cent was observed and in the others there was no rise at all Of the six cases with normal initial counts three showed an increase above

2 per cent either during the period of treatment or in the after-period, the highest figure reached was 4.6 per cent All patients returned to their original levels within a week of cessation of therapy The red cells, hemoglobin and leukocyte levels remained essentially unaffected In none of the nine patients studied only after therapy had started or was completed was there a rise of reticulocytes above 2 per cent Moderate doses of sulfanilamide seem to act as a mild stimulus to the bone marrow Further work is required to determine the relationship of this phenomenon to those cases in which a severe anemia arises

Hormone Content of Ovarian Tumors—Lepper and her colleagues tested the fluid from a number of follicular cysts of the ovary for estrogen The concentration of estrogen in the fluid was of the same order as in the normal ripe follicle Owing to the increased volume of fluid the absolute amount of estrogen in the ovary was considerably increased Characteristic changes were found in the mucous membrane and muscular coats of the uteri These changes may be more evident either in the mucous membrane or in the muscular coat, and sometimes the two structures are equally affected Seventy ovarian tumors and the corresponding preoperative urines were examined for the follicle stimulating and luteinizing factors and estrogen The follicle stimulating factor was found in larger amounts in the cyst fluid and urine in cases of malignant than in cases of innocent ovarian tumors This factor may be found, however, in all varieties of ovarian tumors The luteinizing factor was found in the fluid of the cysts in two of three pregnant patients The only cysts that yielded estrogen were the follicular cysts in which it occurred in a concentration at least as high as in the normal follicle and two specimens of germinal cysts in which the concentration was so low as to suggest that it was the same as in the blood stream The association of menstrual irregularities with follicular cysts has been confirmed Other ovarian tumors are far less often associated with disturbance of the menstrual rhythm Pain in and swelling of the breasts before a period was noted more often in patients with follicular cysts than in patients with other types of benign ovarian tumors

Pellagra Treated with Factor Obtained from Liver—Yudkin and his associates report a case in which pellagra developed in a man with a gastro enterostomy who lived on an eccentric diet The pellagra yielded rapidly to treatment with a filtrate factor obtained by repeated adsorption of liver extract with fullers' earth

Heart and Anoxia—Binet and his associates made experimental studies of mountain sickness on anesthetized dogs. To avoid the influence exerted by the diminution of atmospheric pressure, they used a gas mixture with a deficiency in oxygen but with a pressure of 760 millimeters of mercury. The anesthetized dogs inhaled the gas mixture through a tracheal cannula. The arterial pressure, the electrocardiogram and the respiration were recorded. Their observations reveal the impairment of the heart in acute anoxemia. The graphic recording of the arterial tension suggests the possibility of a cardiac arrest preceding the respiratory arrest. The electrocardiographic records taken in the course of anoxemia reveal five types of disorders: (1) the inversion of the T wave with an anoxemia corresponding to an altitude of 8,000 meters, (2) correspondence of the electromotive force and the duration of this wave, when it has become positive again, to an augmentation to an altitude of 14,000 or 15,000 meters, (3) the marked diminution of the height of the R deflection, (4) the disappearance of the P wave during the apnea caused by the anoxemia or the appearance of an auriculoventricular dissociation, (5) the appearance of a sinus tachycardia at the time of a sudden return to the normal atmosphere.

Observations on Children Having Received BCG—Stevenin and his associates report observations on eighty-one children who had been given BCG by mouth and who remained in a tuberculous milieu. Although these children were not isolated, their tuberculous morbidity was below that of the nonvaccinated children, their mortality from tuberculosis was nil and the cutaneous reaction with tuberculin was more often negative in the children treated with BCG than in those who were not so treated. These observations were made simultaneously in two different dispensaries and they were in perfect concordance with those made in 1930. The authors conclude that not the slightest danger is involved in the administration of BCG to the children by the oral method, even when it is impossible to take all the precautions which are necessitated by this method of prophylaxis against tuberculosis.

- Physiologic Role of Histamine I Marcon E Athanasu Vergu D Chiriacanu G Cosma N Gingold and C C Parhon—p 371

Fibrinogen Content of Blood—Lian and Frumusan describe a technic for the determination of the fibrinogen content of the blood. They combine 15 cc of blood with 0.03 Gm of finely pulverized potassium oxalate. After centrifugation, exactly 5 cc of plasma is put into a precipitation tube containing 100 cc of a coagulating solution that consists of 8 Gm of sodium chloride, 1.25 Gm of calcium chloride and 1,000 cc of distilled water. The mixture is left standing for three hours at room temperature. The time required for coagulation varies. The mass forms a jelly, which is put into a square of fine cloth and is pressed out. When all the liquid has been forced out it is put under a current of water. Then

the cloth is opened and the fibrin is readily detached in form of a small elastic ball, which is washed under a current of distilled water. It has been verified that after this washing the coagulum of fibrin contains no more chlorides but crystals of calcium oxalate, which form as a result of the excess of potassium oxalate employed in the collection of the blood. Then the ball of fibrin is pressed between two thicknesses of filter paper and is dried for six hours at a temperature of 110 C, then it is weighed. The result is the net weight of the fibrin plus the enclosed calcium oxalate. Then the fibrin is placed in a small platinum dish and is subjected to calcination, the ashes are subjected for ten minutes to an extremely high temperature to transform all the calcium oxalate into lime. The ashes are rapidly weighed and from the weight is calculated the weight of the calcium oxalate. To do this, the weight of the ashes is multiplied by 2.60 (the coefficient which corresponds to the calcium oxalate with one molecule of water). When the weight of the calcium oxalate is deducted from the weight of the ball of fibrin, the result is the real weight of the fibrin contained in 5 cc of plasma. The test is made while the person is fasting. In normal subjects the figures were between 4 and 5 Gm per liter of plasma. The authors describe and evaluate the results they obtained with this method. They found it valuable in certain infectious diseases, in some disorders with edema, and especially as a functional test for the liver. They think it should be used for the diagnosis and prognosis of hepatobiliary disturbances. Cirrhosis and icterus of the catarrhal type lead to a notable reduction of fibrinemia, while cancers of the liver and icterus by retention are accompanied by a normal or increased fibrinemia. From the diagnostic point of view, fibrinopenia indicates the cirrhotic nature of a large liver or of an unknown ascites. In icterus, fibrinopenia contradicts an icterus by retention and favors the diagnosis of catarrhal icterus.

- *Renal Complications in Tuberculosis of Bones and Joints H R Lammann—p 200

Surgical Treatment of Vocal Cords in Paralysis of Recurrent Nerve—Luscher points out that the bilateral median position of the vocal cords, resulting from a bilateral paralysis of the recurrent nerve, leads sooner or later to a severe laryngeal stenosis, so that tracheotomy cannot be avoided. All conservative methods of vocal and respiratory exercises should be tried before surgical measures are resorted to. Moreover, surgical injuries to the recurrent nerve in strumectomies often improve spontaneously in the course of months or even years, so that the glottis becomes again sufficiently wide. However, with rare exceptions the final status is reached after one or two years. After enumerating the difficulties that are encountered in widening the glottis, the author mentions the various interventions that have been recommended, nearly all of which have the object of widening the glottis at the level of the vocal cords. However, Wittmaack developed a surgical method which deliberately induces the lowering of one of the vocal cords. In two cases he found Wittmaack's operation a simple and reliable method for the correction of stenosis of the glottis in case of bilateral paralysis of the recurrent nerve with median position of the vocal cords. He would refrain from performing it only if the patient insists on an absolutely normal and clear voice.

Renal Complications in Tuberculosis of Bones—Lammann asserts that the visceral complications of tuberculosis of the bones and joints involve most frequently the kidney and the discharging urinary passages. In the last five years he examined 159 patients with tuberculosis of the bones and joints without visceral complications. He found that 31 per cent had renal complications. Secondary renal tuberculosis therefore assumes an importance as great as that of tuberculous meningitis and of miliary dissemination. The author recommends

that, during treatment of tuberculosis of bones and joints, the examination of the urine for the presence of tubercle bacilli should be a routine measure. Incipient renal tuberculosis causes no symptoms and, when they appear, the lesions usually have advanced so far that further dissemination has to be feared. Early recognition of renal tuberculosis makes early and more successful treatment possible.

*Volume of Circulating Blood During Induced Fever R Traverso—p 61

Volume of Blood During Induced Fever—Traverso found that the volume of blood of normal persons increases in the course of fever induced by the giving of pyretogenic substances. There may be a predominance of erythrocytes over blood plasma, or the reverse. The volume of blood may increase less in persons who react with high fever to the pyrogenic substance than in those who react with slight fever. It is greater during the ascending phase of the fever than during its deferescence. The consumption of oxygen is increased. According to the author, the volumetric variations of the blood are due to special functional conditions of the cardiovascular organs in accordance with the predominance of sympathetic or vagal stimulations. A factor of great importance is the increase of the consumption of oxygen which results in increasing the flow of venous blood to the heart, the cardiac output and the functions of the cardiovascular system. In the phase of deferescence of fever the venous pressure gets lower and the cardiac output and the volume of blood diminish. The author concludes that the factors which stimulate hyperkinesia of the cardiovascular apparatus and mobilization of the blood from blood depots prevail, in the course of induced fever, over those which cause hyposthenia of the cardiovascular apparatus and retention of blood by the blood depots.

- *Bismuth Salicylate in Treatment of Infections of Upper Part of Urinary Tract G Riva Crugnola—p 361
Periodic Psychosis and Invalidism for Work E Rizzatti—p 372

Bismuth Salicylate in Infections of Urinary Tract—Riva Crugnola's treatment for infection of the urinary tract consists in intramuscular injections of 0.1 Gm of bismuth salicylate every other day or 0.2 Gm with intervals of three days between the injections up to a total number which varies from three to twenty injections. The treatment is indicated in cases of grave inflammation of the upper part of the urinary tract with fever, as well as in cases of long duration. The symptoms are ameliorated and the fever disappears after very few injections. The treatment is well tolerated and is not followed by accidents or complications except for a moderate stomatitis in some cases. The results are satisfactory regardless of the type of pathogenic bacteria in the given case. Satisfactory results are reported by the author in ten cases of pyelonephritis or pyonephrosis in which previous energetic medical treatment, the use of a permanent catheter and hypodermoclysis failed.

Puncture in Diagnosis of Cancer of Lung A Lanari and A Pavlovsky—p 625

Puncture of Lung for Diagnosis of Cancer—According to Lanari and Pavlovsky the cytologic study of material taken from the lung by puncture of the structure is of value for an early diagnosis of cancer. The approximate location of the tumor is determined by the roentgen study of the thorax. The puncture and aspiration of tissue are performed with a needle

such as that used for intramuscular injections or for lumbar puncture and a syringe by means of which a moderate aspiration can be done. The material in the syringe or, if there is none, the particles of tissues around the needle are spread on a glass slide, stained with May-Grunwald-Giemsa stain and examined under the microscope. Cancer cells can be identified by their abnormalities. They rarely divide in amitosis. They show abnormal division and uneven distribution of chromosomes. If they are in the phase of rest they show themselves almost as giant cells with alterations of the protoplasm, ruptured relations between the nucleus and the protoplasm and the nucleus and the nucleolus and abnormalities of size, structure and staining properties of the nucleus. Blastomatous cells are identified particularly by their nondifferentiation, which may be total, partial, uniform or polymorphic. The presence of cancer cells in the material which is under examination is the crucial test. Their absence may indicate that the needle failed to reach the cancerous zone. In this case it is advisable to perform a new puncture. It is indicated when the clinical symptoms and roentgen signs show cancer of the lung, whereas the inclusion of sputum of the patient and bronchoscopy give negative results. It is contraindicated in the presence of septic conditions and of echinococcosis of the lung. A diagnosis of cancer of the lung was made by the author in thirteen cases of a group of twenty-four in which the procedure was used. The different aspects of the cells are shown by illustrations in the article.

Foot and Mouth Disease—Wagener discusses the epizootic of foot and mouth disease which in September 1938 was brought into Germany from France, where it had been introduced by transports of Algerian sheep. The cause of the disease is a filtrable virus, which passes all so called ultrafilters and retains its infectiousness in extremely high dilutions (1:10,000,000). Hecke succeeded in 1930 in culturing it on the skin of the fetuses of guinea pigs. Today the cultured virus can be obtained in large quantities. There are at least three varieties (A, B and C) of the virus of foot and mouth disease. Immunity produced by one type is not effective against the other types. The transmissibility to man has been demonstrated. After an incubation period of from three to four days, the human form of the disease shows the same two phasic character and the febrile course that is observed in animals. In the local manifestations it is usually possible to differentiate in the time of appearance between the formation of the primary blisters and the later generalization. The primary blisters develop at the port of entry, on the lips, the oral mucosa and the hands. The exanthem of mouth and foot disease consists of vesicles of various sizes, which develop rapidly, burst and heal without leaving traces. In case of nonfebrile disorders that are restricted to the oral cavity, the diagnosis of mouth and foot disease should be made with care. The diagnosis can be corroborated by introducing material from the blisters into the scarified skin of the plantar surface of the posterior extremities of guinea pigs.

Sternal Puncture in Diagnosis of Infections—Baserga and Barbagallo aim to demonstrate that the intravital examination of the bone marrow is valuable in general infections, it is often positive when the examination of the blood is negative. Sternomedulloculture has produced good results in cases of brucellosis more particularly in Malta fever (*Brucella melitensis*). It was observed that whereas the blood culture is frequently negative the sternomedulloculture is nearly always positive during the acute stage. Whereas the blood culture reveals positive results as a rule only in cases in which the temperature exceeds 39 C (102.2 F), the medulloculture gives positive results even if the temperature is only in excess of 37.5 C (99.5 F). They cite several case reports and point out

that medulloculture in cases of brucellosis proves that the bone marrow is a focus for the brucella organisms even during the nonsepticemic period. Attention is called also to the diagnostic significance of medulloculture in abdominal typhoid. Observations in more than 100 cases (made by the authors and other investigators) revealed the superiority of medulloculture over blood cultures. The bacillus disappears much later from the bone marrow than from the blood.

Question of Harmful Properties of Cigaret Paper —

Wenusch and Scholler state that the charge has been made repeatedly that cigaret paper produces harmful combustion products. Experiments have been reported to show that the smoke of cigarets, as a result of a higher carbon monoxide content, has a blood pressure increasing action. The authors, however, proved in earlier experiments that a carbon monoxide concentration, which is much higher than that in the smoke of cigarets, causes no increase in blood pressure. The authors made experimental studies which revealed that the paper of a cigaret of the usual size weighs approximately 0.04 Gm and that this quantity cannot develop much in excess of 1 cc of carbon monoxide. The negligible physiologic significance of this amount becomes more convincing when it is considered that it is distributed over approximately twenty drafts. The authors point out further that a cigaret weighing 1 Gm gives off approximately 20 cc of carbon monoxide, this quantity, distributed over an average of twenty drafts, signifies that approximately 1 cc of carbon monoxide is taken in with each draft. Since one breath carries approximately 500 cc of air, those inspirations during which smoke is inhaled have a carbon monoxide content of 0.2 volume per cent. However, after each breath containing this amount there are from seven to eight inspirations that are practically free from carbon monoxide. The accumulation of carbon monoxide in closed rooms in which considerable smoking is done is usually estimated too high.

- Close Roentgen Therapy in Malignant Tumors A H Roffo and D Giudice —p 237
- Ultraviolet Rays and Cancer F Holtz —p 238

Close Roentgen Therapy—Chaoul reviews the efforts made to improve the depth action of roentgen rays and later to imitate the action of radium rays. To make the action of roentgen rays similar to those of radium rays, the first requirement is to make the spatial distribution of the energy of roentgen rays in the tissues similar to that of radium rays. The author accomplishes this by close roentgen therapy with low voltage. He uses the relatively low tension of 60 kilovolts with a filtration of 0.2 mm of copper and distance of from 3 to 5 cm. Two other factors in which the former type of roentgen therapy differed from radium therapy was the time factor and the total dosage. The author shows how these factors are altered in the technic of the close irradiation with low voltage and demonstrates that in close roentgen irradiation conditions are created which largely resemble those in contact radium therapy. To enlarge the sphere of application, a modification in the form of short distance roentgen therapy was developed as a substitute for the radium distance therapy (radium bomb). The author discusses the results obtained with the new form of roentgen therapy in six years. The method was employed chiefly in carcinomas of the skin and of the lips. In one table are recorded not only the cases treated at his own clinic but those of several other clinics. This table lists 595 cases and shows that in 95.4 per cent of the cases primary freedom from symptoms was obtained. He describes the results of close roentgen irradiation in cases of exposed carcinoma of the rectum. Nearly all of the fourteen cases treated with this method were inoperable, but primary freedom from symptoms was achieved in twelve of the fourteen cases.

Close Roentgen Therapy at Low Tension—In this report, Woodburn Morison and Bryan Adams report their experiences with Chaoul's method of close roentgen therapy

at low tension. They show that it fulfils one of the requirements of radiation therapy, namely, it destroys the diseased tissues and preserves the healthy tissue. With the apparatus they used, the dose is easily regulated and permits of variations. In cases of rodent ulcers they usually apply 4,800 roentgens to the base of the tumor. Distributed over a period of ten days, the total surface dose usually amounts to 6,000 roentgens. In other cases of rodent ulcer the 6,000 roentgens was administered at once or in three installments. The results seemed to be better when the dose of 6,000 roentgens was distributed over ten days. In cases of squamous cell carcinoma, the authors apply a dose of 6,000 roentgens to the base of the tumor. This dose is likewise distributed over ten or twelve days. To adenocarcinoma they apply from 7,000 to 10,000 roentgens in the course of twelve days. Malignant tumors are treated with from 10,000 to 15,000 roentgens. For malignant tumors, such as papillomas, are usually treated with a single dose of 4,000 roentgens. Cicatricial keloids respond to a daily dose of 400 roentgens and to a total dose of from 2,400 to 3,000 roentgens. On the basis of two years experience with the close roentgen therapy at low tension, the authors are convinced that it represents the most valuable addition to roentgenology in recent years.

- *Acetonemic Vomiting with Fatal Outcome Irmgard Scharff —p 51

Prognostic Significance of Rest Nitrogen in Diphtheria—Hoffken says that his observations demonstrated that the determination of the rest nitrogen in patients with diphtheria is of no value for prognosis. Rest nitrogen values give no definite indications regarding the possible development of complications, even those of a severe nature. In two fatal cases of toxic diphtheria he observed that the rest nitrogen values became high only when the clinical picture indicated the fatal outcome. In the severe cases in which the prognosis is especially doubtful he found that the rest nitrogen values fluctuated greatly.

Antitoxin Following Immunization with Diphtheria Toxin—To determine the effectiveness of precipitated vaccines, Kreutzer investigated the antitoxin formation following their administration. He made his tests with a diphtheria toxin, 1 cc of which contains 95 protective units. He vaccinated children between the ages of 6 and 14 years. The investigations revealed that a single injection of the diphtheria toxin produces adequate antitoxin values in 82 per cent of the children. This favorable result can be improved still more when the quantity of vaccine to be injected is divided into two doses administered with an interval of four weeks. The author thinks that his results justify active immunization against diphtheria.

Acetonemic Vomiting with Fatal Outcome—Scharff reports the histories of five cases of acetonemic vomiting which terminated in death. All cases showed the same symptoms. Acetone was detected in the respiratory air and in the urine. The attacks of vomiting developed without other demonstrable causes. In all the children the vomiting had persisted for one or several days before hospitalization, so that when the children reached the clinic they were already in an extremely dehydrated and somnolent condition. It was possible to arrest the vomiting and to introduce by mouth fluids, salt and sugar. The cessation of vomiting and these measures resulted in an improvement which however, was of short duration. The subsequent exacerbation was characterized by renewed vomiting. Whereas previously the stools had been normal or absent, they were now frequent and resembled rice water. The fact that these stools had an extremely high sugar content is considered as proof that during this final stage of the disease the resorption capacity of the intestine is impaired. Necropsies were made in four of the five cases and fatty degeneration of the liver was found in all. The author suggests that degeneration of the liver is the

final result of disturbance of the carbohydrate and fat metabolism. She calls attention to the role of the adrenals in the exchange of sodium chloride and in the resorption capacity of the intestinal mucosa. Since acetoneuria is favored by the absence of the adrenocortical hormone, the author suggests that during the threatening stages of acetonemic vomiting adrenal cortex extract might be tried in addition to the infusions of sodium chloride.

Determination of Vitamin C—Rotter says that, whereas Cavitaminosis is rare C-hypovitaminosis is frequent. He directs attention to the role of vitamin C in hemorrhages, in diseases of the blood and in infectious diseases, particularly pneumonia, and also to the interesting fact that cancer tissue contains comparatively large amounts of vitamin C. In his own studies on the vitamin C content of the blood and urine he resorted to titration by dichlorophenolindophenol. It occurred to him to simplify matters by injecting blue dyestuff into the skin, forming a small wheal, and then watching the reducing action of the vitamin C (cevitamic acid) on the dyestuff. Injecting into the plantar skin of guinea pigs with and without scurvy small amounts of a normal 1,000 solution of dichlorophenolindophenol, the author observed the behavior of the resulting wheals. He found that in the skin of the animals with scurvy the discoloration required four times the length of time required in healthy animals. He investigated whether the process of discoloration is a chemical process, a reduction or a biologic process, a resorption. He describes studies on patients which proved that the reduction of dichlorophenolindophenol in the intracutaneous wheals is effected by cevitamic acid. A normal 400 solution of dichlorophenolindophenol was best suited for the intracutaneous injection. The wheal should be about 2 mm in diameter. When this technic was used, it was found that a reduction time of less than five minutes indicated saturation and of between five and ten minutes a normal supply, but that a reduction time in excess of ten minutes indicated a deficiency. The author maintains that this simple method, which can be used by the practitioner, can be substituted for the rather complicated tests on the blood and urine. He proved this by comparative control experiments.

Problem of Cyanosis in Congenital Cardiac Defects of Early Childhood K Hochsinger —p 235
Microscopically Visible Changes in Conadal Tissue Following Ligation of Deferent Duct K John —p 237

Indications for Surgical Treatment of Gastric Hemorrhages—Finsterer summarizes his point of view on the treatment of acute gastric hemorrhages as follows. 1. In acute hemorrhage from a definitely demonstrated ulcer he advises immediate operation because that is the most reliable method for the arrest of the hemorrhage. It prevents fatalities resulting from later erosion hemorrhages due to a burrowing ulcer and it also prevents perforation into the free abdominal cavity. A preoperative or postoperative blood transfusion is necessary only in severe hemorrhages resulting from erosion of a large

artery. 2. If after failure of internal treatment an ulcer persists in bleeding, the author recommends late operation. In cases in which it is doubtful whether the hemorrhage persists, he recommends an expectant attitude, because the prolonged anemia has so impaired the internal organs that even after blood transfusion the operation may be a failure. 3. In case of acute hemorrhage from a probable ulcer he recommends an exploratory laparotomy under local anesthesia, so as to exclude a penetrating ulcer. If an ulcer is detected the resection should be done in the typical manner. In case of a hemorrhage that is the result of an erosive gastritis, the resection is advisable if the disorder has existed for many years and relapses constantly, otherwise the abdomen is closed and the internal treatment is continued. 4. If the hemorrhage appears suddenly, without the slightest previous disturbances, an acute, flat ulcer is probably the cause. In this case internal treatment is advisable. If the loss of blood is considerable or the hemorrhage recurs, the internal treatment should be supported by a blood transfusion. 5. If the existence of a hepatic cirrhosis is certain, exploratory laparotomy seems advisable, if only the slightest gastric disturbances (e.g., heartburn) have preceded because, on account of the stasis, the patient may bleed to death even from an eroded vein of a flat ulcer. 6. When hemorrhage occurs in elderly patients (beyond the age of 60 years) or in an existing arteriosclerosis the author considers surgical treatment even more urgent than in young persons.

Changes in Gonads Following Ligation of Deferent Ducts—John ligated the deferent ducts of rats, rabbits and guinea pigs and studied the histologic changes in the testes and epididymides. He found that at first there are no changes but that then hypertrophy becomes noticeable. The first signs of hypertrophy appear in guinea pigs and rats after six weeks and in rabbits after eight or ten weeks. The tubuli contorti are filled with spermatozoa and the testes are slightly swollen. This stage of excessive filling gradually subsides and after a time the testicular tissue appears normal once more. However, other processes are now in preparation. The reduced elimination of the sexual products effects changes first in Sertoli's cells, their plasma gradually disappears, while the nucleus becomes enlarged at first but later shrinks and disintegrates. At the end of ten or twelve months hardly any intact Sertoli cells remain. The author discusses the changes in the seminiferous tubules and those in the interstitial tissue or Leydig's cells. The latter likewise become atrophied. The tissues of the epididymides, however, show a different behavior from those of the testes. The total sterilization of the animals by ligation of the deferent ducts, is followed by a gradual obliteration of the generative tissues, which necessarily leads to abolishment of the sexual functions. Thus ligation actually produces sterilization, but it also impairs such sexual functions as libido and potentia coeundi. The author emphasizes that the changes in the gonads do not develop so rapidly that they could be completed within a few weeks. He found that in the experimental animals the final stage has not been reached until at least twelve months has elapsed since the ligation of the deferent ducts.

Pregnancy, Labor, Abortion and Gonorrhea—Kushelevskiy reports a clinical study of two groups of women carried out in the Moscow Institute for Protection of Motherhood. The first group comprised 876 obstetric cases while the second consisted of 450 pregnant women who wished to be aborted (this work was done prior to 1935). The author feels that much can be done by the obstetrician-gynecologist to diminish the

incidence of gonorrhea by diagnosing and treating cases among the obstetric patients admitted to maternity hospitals, dispensaries and consultation stations. Patients in whom the diagnosis of gonorrhea was made were treated and kept under observation during gestation and after, the total period being not less than two years. The symptoms of gonorrheal infection in pregnant women did not present pathognomonic signs of the disease. The diagnosis could be arrived at only after detailed clinical and laboratory investigations. This was particularly true of the chronic cases. Despite the more severe character of the disease during pregnancy and the postpuerperal period, smears were positive in only a few cases. The repeatedly positive Bordet-Gengou serologic test proved to be valuable. A greater number of complications took place in cases in which conception took place in the presence of an ascending gonorrheal infection and in cases in which gonorrheal infection developed toward the end of the gestation. Artificial abortion in gonorrheal patients results in complications in from 30 to 33 per cent. Women in whom gonorrhea was demonstrated were given a systematic treatment consisting of local applications, physical therapeutic measures, gonorrheal vaccine and autohemotherapy. Disappearance of the infection and return to a working capacity were obtained in the majority of cases.

Intracranial Tumors—Of the 353 cases of intracranial tumor, of which 154 were verified on operation or at necropsy, 189 were in male and 164 in female patients. Five patients were under the age of 5 years and none were over 66, the greatest frequency was in the age group from 36 to 40. Torkildsen says that the most important symptoms named by the patients were, in order, headache, vomiting, paralyses of cranial nerves, dizziness, loss of vision, focal epilepsy and pareses of extremities. Objective examination on admission showed mental disturbance in 190 cases (53 per cent). Of the pareses of the cranial nerves the most common were those of the nerves of the eye muscles and of the facial nerve, together with reduced function of the optic nerve. Choked disk was present in 200 cases. In 153 of 167 cases the cell content of the spinal fluid was less than 15/3, in 122 out of 161 the albumin content was less than 1/25 and in 127 out of 154 the globulin content was less than 1/3. The pulse frequency was 50 or less in four cases, between 50 and 60 in eighteen, and more than 90 in forty-eight. There were no special peculiarities in pulse frequency in relation to age. No connection was seen between high blood pressure and high pressure of the spinal fluid.

Myelomatosis—Grut's case was characterized by unusually high serum proteinemia, rapid formol-gel reaction, absence of coagulum reaction, infiltration of organs by plasma cells and rapid clinical development. The diagnosis was verified by sternal puncture. Bence Jones proteinuria was confirmed by careful examination. He considers (1) myelomatosis with change

only in the bone marrow but spread diffusely through the lymphatic system, (2) myelomatosis with limited tumors in bone marrow and bone substance and (3) myelomatosis with diffuse infiltration of bone marrow and bone substance, eventually involving organs, by tumor cells. The first and third forms differ widely in the intensity of the pathologic changes. With slight intensity of the process, transition from the first to the second form is thought likely, with considerable intensity, as in the case reported, there is direct transition from the first to the third form, with fatal outcome in a short time. In the first form the symptoms are vague and the characteristic picture does not appear until there are localized multiple myelomas. Examination of the blood gives no information. The x-ray reactions are not pathognomonic. Increase in the serum globulins, however, is characteristic, only one case of myelomatosis with normal sedimentation and formol-gel reaction has been described. These two reactions are thus of the greatest practical value in the diagnosis of myelomatosis. In 50 per cent of the cases there is Bence Jones proteinuria, which occurs only occasionally in other disorders, it can be established in 80 per cent of the cases if examinations are frequent and made for months. Establishment of the protein may be difficult if simultaneously abundant serum albumin is present in the urine. Certain diagnosis depends on sternal puncture. Sedimentation reaction is called for in all cases with resistant pain in the back, formol-gel reaction in all afebrile patients with high sedimentation reaction, and if the formol-gel reaction is positive, sternal puncture is indicated. The formation of the serum globulins and Bence Jones protein is assumed to take place in the bone marrow, especially in its plasma cells. The high hyperproteinemia in the author's case is ascribed to penetration of not only the bone marrow but also numerous organs by the plasma cells. The quantity of the tumor cells and not their quality apparently determines the degree of hyperproteinemia.

*Danish Family with Cameloid Blood Corpuscles (Constitutional Elliptocytosis) Ovalocytary Anemia A. Bertelsen—p 136

Danish Family with "Cameloid" Blood Corpuscles—Bertelsen says that elliptocytary or ovalocytary anemia easily escapes clinical recognition and that its frequency is unknown. At present ten reports on constitutional elliptocytosis have been reported, concerning either cases in which the elliptic deformity of the red blood corpuscles was accidentally discovered and not believed to be connected with any disorder or cases in which it is regarded as the disposing cause of long continued anemia and febrile conditions. Familial occurrence of twelve cases of elliptocytosis in four generations is here reported, including one case of grave elliptocytary anemia in a boy, aged 3 years, observed for a considerable time. The most marked elliptocytotic pictures were in the boy and his mother, but in no case was the diagnosis in doubt. The number of deaths in childhood in the family has not exceeded that in most families. Elliptocytosis is regarded as a constitutional anomaly with dominant transmission, but the hereditary relations are still largely unsolved. In no reported case have the anemia and its complications been fatal. When a true anemia accompanied by chronic infection has developed, the disease has been of unusually long duration. Except in Roth and Jung's case, the later fate of the patients is unknown. In four of the seven cases clinically described, the liver and spleen were enlarged, in two splenomegaly was a prominent symptom, and in two there was jaundice. On examination in the counting chamber the form of the blood corpuscles may pass unnoticed and in smears the deformity may perhaps be considered an artificial product and disregarded as an unimportant or peculiar form of anisocytosis. In chronic sepsis with enlargement of the spleen and anemia, complete examination of the blood with this anomaly in mind is advised. The elliptocytosis itself does not seem amenable to any therapy. Hunter and Adams report improvement of the anemia after treatment with liver extracts, and Roth and Jung after treatment with solution of potassium arsenite. The author found that similar treatment was of doubtful value in the case that he reports, but blood transfusion helped the patient through a critical period.

STATISTICS ON DEATHS FROM RHEUMATIC HEART DISEASE

HALBERT L. DUNN, M.D., PH.D.

Chief Statistician for Vital Statistics Bureau of the Census

WASHINGTON, D. C.

AND

O. F. HEDLEY, M.D.

Passed Assistant Surgeon United States Public Health Service

PHILADELPHIA

The Bureau of the Census publishes mortality statistics according to the titles of the International List of Causes of Death. This list has been accepted internationally for over forty years. It is modified at each decennial revision by means of an international conference, the next meeting of which will be in the fall of this year. This revision is necessary in order to realine the list with advances in the science of medicine.

Two distinctly different points of view are in conflict with each other in the revision of this list. From the standpoint of physicians on the frontier of modern medicine, the essential desire is to change the titles so as to produce statistics which meet the requirements introduced into the picture of death by the new and advanced knowledge of medicine. Each modification of the list made with the purpose of meeting the demand for change disturbs the comparability of the mortality statistics produced by the use of the list, so that it becomes increasingly difficult to study the significance of changes in the death rates for various conditions from one decade to another. On the other hand, the physician desiring change says "What use is it to maintain comparability if the titles are relatively meaningless in the light of the newer knowledge of medicine?"

An assumption commonly made by both the physician and the statistical analyst is that the problem of securing comparability in mortality statistics will be solved if satisfactory readjustments can be made in the International List of Causes of Death. While it is true that such adjustments are essential in order to modernize the list and to bring it into line with advances of medicine, other factors are also involved in the production of statistical comparability of the tabulations. Among these factors are such items as the changing habits of the physician in the diagnosis of disease, the increase in his knowledge and the new scientific tools at his disposal for diagnosis, and the methodology in the selection of the primary cause of death when several causes are noted on the certificate.

From the Office of Vital Statistics, Bureau of the Census, United States Department of Commerce, and the Office of Heart Disease Investigations, branch office of the National Institute of Health.

Students of heart disease have been at a disadvantage because of the lack of mortality statistics tabulated on the basis of what is now an accepted entity, rheumatic heart disease. The International List of Causes of Death classifies the various heart conditions on an anatomic basis, whereas it is now generally accepted that rheumatic conditions should be treated as a unit, since they have a common etiologic basis. It has become increasingly important that this particular group of heart diseases be studied as a class, since cardiac mortality as a whole has been increasing over the past two decades.

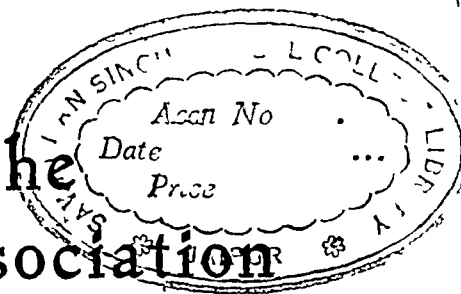

One of us, an officer of the United States Public Health Service assigned to the Office of Heart Disease Investigations, has been responsible for focusing the attention of physicians on the need for change in the tabulations of rheumatic heart conditions. His contributions were emphasized in an editorial in THE JOURNAL of Jan 9, 1937.

At the present time the International List of Causes of Death classifies acute rheumatic fever separately as title 56. Other rheumatic heart conditions are included without separate notation under the titles pericarditis, chronic endocarditis, diseases of the myocardium and other diseases of the heart.

The Bureau of the Census has agreed to separate rheumatic conditions under each of these titles for the death certificates of 1937, 1938 and 1939. For these years heart conditions will be tabulated in two ways as they have been listed in the past, so that comparability can be retained, and also, in accordance with the needs of the cardiologist, as separate rheumatic conditions. The accompanying table constitutes the office breakdown to be used by the Bureau of the Census in the tabulations for the years mentioned. The changes affecting rheumatic heart disease are listed in italics.

The proposed regrouping of deaths from heart conditions to be used by the Bureau of the Census in the tabulations of 1937, 1938 and 1939 is an office breakdown and does not constitute official changes in the International List of Causes of Death. However, the American Public Health Association committee on the accuracy of certified causes of death has incorporated a similar modification as a part of its recommendations to be made to the international commission for the revision of the International List of Causes of Death in Paris this fall. What can be achieved in effecting a permanent reclassification of the rheumatic conditions will not be known until the results of the meeting of the international commission are obtained.

There is little doubt that an entirely new picture will result from the separate tabulation of rheumatic cardiac conditions. In preliminary studies conducted by the United States Public Health Service in Philadelphia, practicing physicians in that city were requested

to report deaths from rheumatic heart disease during 1936. The number reported was 357, which would indicate a death rate for Philadelphia of 176 per hundred thousand of population. In addition there were 195 deaths which might or might not have been

due to a rheumatic condition, e g, those due to subacute bacterial endocarditis, to endocarditis in persons under 30 years of age, to valvular disease of long duration in persons over 30, to mitral stenosis and to other conditions encountered less frequently.¹

Since plans have been made to tabulate rheumatic conditions in such a manner that the statistics will be of greater value to the medical profession, it is urged that practicing physicians throughout the United States report deaths from rheumatic heart disease whenever the rheumatic origin can be determined. Unless they are reported as such on the death certificate, the deaths cannot be tabulated as rheumatic. Whenever possible the general term "rheumatic heart disease" should be qualified by designation of the specific anatomic lesion, i e, "rheumatic heart disease, mitral stenosis." In view of the increasing interest in rheumatic heart disease, it should not prove difficult for physicians to specify the rheumatic origin. Practically every article in the medical literature dealing with this disease and every textbook on the subject written during the past fifteen years has stressed the etiologic point of view. Immediate death resulting from acute rheumatic fever is relatively infrequent. Swift estimated the rate to be from 1 to 4 per cent. Such death occurs almost always as a result of rapidly progressive carditis. However, deaths from longstanding rheumatic disease are numerous and should be specified. Experience has shown that a history of rheumatic fever or chorea can be obtained in only about 50 to 75 per cent of the cases of rheumatic heart disease. Not infrequently rheumatic heart condition develop insidiously or else the patient fails to remember mild attacks of rheumatic fever or chorea. Language difficulties or the condition of the patient sometimes prevent the physician from obtaining a satisfactory history unless special care is taken.

By means of necropsies and microscopic examinations a large proportion of the conditions diagnosed as mitral stenosis, the majority of those diagnosed as aortic stenosis and adherent pericardium, in combination with other valvular lesions, and valvular disease of any type of long duration have been proved to be of rheumatic origin. It is desirable that a necropsy be performed whenever possible if the diagnosis is questionable, so that the condition can be established as rheumatic or nonrheumatic.

A number of conditions must be differentiated from rheumatic heart disease. Chief among these are congenital cardiovascular defects, especially in children syphilitic aortitis with or without aortic valvular insufficiency, aortic stenosis which may be the result of calcareous changes, aortic insufficiency from arterial hypertension or arteriosclerosis, and pericardial involvement due to pyogenic infections or tuberculosis. Except when there is a history of rheumatic infection or heart disease of many years' duration, extreme caution should be used in diagnosing rheumatic heart disease solely on the basis of systolic mitral murmurs, especially when they are associated with congestive heart failure, arterial hypertension, anemia or a rapid heart action due to hyperthyroidism or other causes.

Infectious septic or metastatic arthritis are not infrequently misdiagnosed as rheumatic fever. Not only acute bacterial endocarditis occurring as a result of pyogenic infections but also gonococcal endocarditis should be differentiated from rapidly progressive rheumatic endocarditis and subacute bacterial endocarditis superimposed on rheumatic heart disease.

SUMMARY

Changes have been made in the method of tabulating deaths from heart disease to provide for the separate

tabulation of deaths from rheumatic heart conditions. The application of these changes began with the tabulation for January 1937.

Physicians throughout the United States are requested to report deaths from rheumatic heart disease as such and to qualify the term when possible by specifying the anatomic lesion in accordance with the regrouping listed in the table.

POSTOPERATIVE CORONARY ARTERY OCCLUSION

ARTHUR M. MASTER, MD

SIMON DACK, MD

AND

HARRY L. JAFFE, MD

NEW YORK

For some years we have been impressed by the association of operation and coronary artery occlusion in patients over 50 years of age. In our previous papers¹ evidence was presented indicating that there was no relationship between the onset of coronary occlusion and exertion, excitement, meals, rest and the like. Operation, on the other hand, was considered probably a precipitating factor. In order to investigate this problem more fully we have collected records of all cases of postoperative occlusion observed at the Mount Sinai Hospital in New York during the years 1931 to 1937. They emphasize the importance of operation in inducing occlusion, and the following analysis attempts to determine which elements of the surgical procedure lead to it.

The association of operation and coronary artery occlusion has been stressed in the past only by Saphir and his associates.² Several authors³ have stated that coronary occlusion in patients with coronary sclerosis may follow operation. In a series of 192 operations,⁴ five deaths were attributed to coronary occlusion subsequent to the operation. From time to time specific instances of coronary occlusion following an operation or a minor surgical or laboratory procedure, such as gastrointestinal x-ray examination or intravenous injection, have been noted.⁵ But none of these authors have attempted to give evidence that the operation precipitated the occlusion.

ANALYSIS OF CASES IN WHICH THERE WAS POSTOPERATIVE OCCLUSION

Incidence and Diagnosis.—During the years 1931 to 1937, 625 attacks of coronary artery occlusion were treated in the Mount Sinai Hospital. Thirty-five, or 5.6 per cent, of these attacks followed an operation in the hospital (table 1). In every instance the presence of the occlusion was proved by postmortem examination or by electrocardiogram. Thirteen additional cases in which coronary occlusion was diagnosed by the surgeon or medical consultant have been omitted because of the lack of postmortem and electrocardiographic examination.

The diagnosis of coronary artery occlusion following operation is frequently difficult, since the very severe pain ordinarily associated with this condition may be absent, it was present in only two fifths of our cases. This disparity may be accounted for, in part, by the liberal use of narcotics and sedatives after operation. Postoperative coronary occlusion is usually ushered in by shock, with dyspnea and cyanosis, and must therefore be differentiated from surgical shock and, in particular, from shock resulting from pulmonary embolism, a differentiation which may be impossible clinically. In certain cases of pulmonary embolism, even the electrocardiogram, if only one is obtained, may resemble that recorded in cases of infarction of the posterior surface of the heart. Because of this uncertainty in clinical diagnosis our report includes only the thirty-five cases in which the electrocardiogram was definite or postmortem examination was performed.

Age and Sex.—Almost two thirds of the patients were 60 years of age or older, the average age was 62. Only four were less than 50 (table 2). Thus postoperative occlusion occurred in the older age groups, in which coronary artery disease is apt to be more prevalent.

The ratio of men to women was 48:1, although the total number of operations in the hospital was equally divided between the sexes.

Previous Cardiac Disease.—Evidence of moderate to severe coronary artery sclerosis was found in all but three of the cases in which a complete history, physical examination and electrocardiographic study were recorded. A history of angina pectoris or dyspnea was frequent, and eight patients had a record of previous coronary occlusion. In thirteen cases hypertension and cardiac enlargement were of long standing. Electrocardiograms were obtained before operation in thirteen cases, and eleven presented definite abnormalities in the T wave and QRS complex. Finally, sclerosis and narrowing of the coronary arteries were present in all cases that came to necropsy.

Time of Occlusion.—Fifty-one and five-tenths per cent of the attacks of postoperative coronary artery occlusion occurred within three days after the surgical procedure (table 3). In six of these cases the onset occurred during the first twenty-four hours, in five on the second day and in seven on the third. Of the remaining attacks, fifteen occurred prior to and two during the third week. Several cases in which occlusion occurred after the third week were not included although the attacks may have been related to the operation. It is thought⁶ that coronary artery

6. Feil Harold. Preliminary Pain in Coronary Thrombosis. *Am. J. M. Sc.* 103: 42 (Jan.) 1937.

occlusion may be preceded for several days or weeks by premonitory symptoms, suggesting a gradual formation of the thrombus

Type and Duration of Operation—As may be seen in table 1, coronary occlusion may follow any type of surgical procedure. While most of the operations were

of major severity, such as resection of portions of the gastrointestinal tract, cholecystectomy and prostatectomy, occlusion occasionally followed a minor procedure, such as paravertebral block and drainage of a phlegmon. Other operations included iridectomy, mastoidectomy, tracheotomy, thyroidectomy and hemi-

TABLE 1—Clinical Data of Thirty-Five Cases of Postoperative Coronary Artery Occlusion

| Case | Sex and Age | Onset Postoperative | Operation | Anesthesia | Postoperative Complications | Symptoms of Attack | Electrocardiogram | Outcome | Necropsy |

* Left anterior descending artery

orrhapy Similarly, the length of the operation varied from ten or fifteen minutes to several hours. Thirteen operations lasted one-half hour or less, twelve from one-half to one hour and ten from one to two hours.

Anesthesia—Postoperative occlusion was not associated with any particular type of anesthesia. Local anesthesia with procaine hydrochloride was administered in twelve cases, spinal anesthesia in ten and inhalation of nitrous oxide, ether or ethylene in five. A combination of inhalation with local anesthesia was employed twice, with spinal anesthesia twice and with avertin with amylene hydrate four times. Thus a variety of types, with manifold effects, was used.

Postoperative Shock—Surgical shock, as manifested by tachycardia, low blood pressure and the like, was present in three fifths of the patients, in half of these it was mild. Only five times did the occlusion manifest itself during the stage of shock.

Intravenous Fluids—Ten patients were given fluids by continuous drip for from one to three days after the operation. The amount was usually less than 2,000 cc daily. In eight of these patients the occlusion occurred during, or soon after cessation of, the infusion.

Bed Rest—The duration of stay in bed was determined, since, as in postoperative peripheral venous thrombosis, it might be significant in coronary artery occlusion. However, the occlusion occurred on the day of operation in eight patients who were ambulatory up to the time of operation. Seven patients were in bed from one to five days before the occlusion, four patients for one week and almost half the group more than one week.

Mortality Rate and Causes of Death—Sixty-six per cent of our thirty-five patients died, in five cases the diagnosis was made only at necropsy. This high mortality is due, in part, to the exclusion from our series of patients who survived the attack but in whom the diagnosis could not be confirmed. In eight of the twenty-three fatal attacks death was the direct result of the occlusion, in the remainder, other conditions, such as pneumonia, uremia, peritonitis and sepsis, were sufficient to produce death, and the occlusion was a

contributory factor. In only one case and evidence of old occlusion was present in less than a third of the group, whereas in coronary occlusion in general, death usually is associated with multiple occlusions. Death in postoperative occlusion, when only one occlusion is present, is usually produced by or in combination with some other condition.

COMMENT

In this series of thirty-five cases of postoperative coronary artery occlusion there are several cogent reasons to support the belief that the operation pre-

TABLE 3—Time of Onset of Postoperative Coronary Artery Occlusion

| Days After Operation | Number |
|----------------------|------------|
| 1 to 3 | 18 (51.5%) |
| 4 to 7 | 4 (11.4%) |
| 8 to 14 | 11 (31.4%) |
| 15 to 21 | 2 (5.7%) |

cipitated the attack. In the first place, the fact that in one half the cases the occlusion occurred within three days after the operation, and in six during the first twenty-four hours, seems to indicate a direct association. Secondly, in eight years there have been only four instances of coronary artery occlusion among patients who have been in the medical wards for long periods because of chronic illnesses such as peptic ulcer, carcinoma, infections and blood dyscrasias. Were the original illness and rest in bed factors in the production of the occlusion, this condition would develop more frequently in such patients. In the third place, during the period in which our collected postoperative cases occurred, the total number of attacks of coronary artery occlusion treated in the hospital was 625. Therefore the thirty-five proved attacks following operation comprised more than 5 per cent of the total, and we believe that this incidence is significant. The actual incidence is doubtless greater than 5.6 per cent, if one bears in mind the thirteen patients who had probably suffered an occlusion but were omitted from the series because of the lack of electrocardiographic or post-mortem confirmation of the clinical diagnosis. Moreover, occlusions occurring after the third postoperative week were excluded, although it is possible that they were related to the operation.

The manner in which operation precipitates coronary artery occlusion is obscure, as is the mechanism of the formation of occlusion of the coronary artery in general, and therefore a discussion of this aspect of the problem is entirely speculative. Coronary artery occlusion is an end result of long standing, progressive sclerotic changes in the coronary vessels. It follows operation only when definite sclerosis of the coronary artery is present, as was demonstrated in our cases by preoperative electrocardiograms and post-mortem examinations. Occlusion occurs usually in persons in the seventh decade or older, when the sclerosis is advanced and the arteries are more liable to acute damage following operation.

It has generally been assumed that thrombosis on an arteriosclerotic plaque is the anatomic basis of acute coronary artery occlusion. However, the recent work of Winternitz and his co-workers⁸ emphasizes the importance of hemorrhage into the plaque as a

TABLE 2—Incidence, Sex and Age Distribution of Postoperative Coronary Artery Occlusion

| | |
|--|------------|
| Number of postoperative attacks | 35 |
| Incidence in 625 attacks of coronary occlusion | 5.6% |
| Sex | |
| Males | 29 (4.8:1) |
| Females | 6 |
| Age | |
| 40-49 years | 4 |
| 50-59 years | 9 |
| 60-69 years | 14 |
| 70-82 years | 8 |

contributory factor. As a rule death occurred after the more severe operations. In two cases death was instantaneous and in seven it occurred on the same day as the coronary occlusion.

Postmortem Examinations—In nineteen cases necropsy disclosed definite sclerosis of the coronary artery. Acute occlusion was found in fifteen cases, acute infarction without occlusion in three cases, and stenosis of the right coronary ostium with infarction in one case. The conditions found varied from those previously reported in a large series of cases of coronary artery occlusion⁷ in that multiple acute thrombi were present

cause of the occlusion. Whether thrombosis or hemorrhage takes place, it may be attributed to alterations in the coronary circulation, such as changes in volume, pressure and speed of flow within the arteries and in the physical and chemical properties of the blood. Such changes undoubtedly occur following operation when some degree of shock, tachycardia and dehydration frequently exists. Shock is associated with a diminution in blood volume and a drop in blood pressure.⁹ The venous return to the heart and the cardiac output are reduced. These factors may result in a decrease in the speed and volume of the coronary blood flow. Tachycardia also may produce an absolute or relative insufficiency of coronary circulation, since it shortens diastole and increases the oxygen need of the heart.¹⁰ This effect is greatest in the presence of sclerotic coronary arteries. Dehydration, like shock, is associated with a diminution in blood volume and in addition with an increase in viscosity of the blood. As we have suggested all these factors may initiate changes in the walls of the coronary arteries leading to occlusion by hemorrhage or thrombosis.

Occasionally the diminution in coronary blood flow may be severe enough to produce ischemia of the myocardium resulting in myomalacia in the absence of occlusion. We have noted three such cases in our series.

Two additional factors associated with operation may be of significance in postoperative thrombosis. The first of these is the liberation of substances affecting the composition of the blood or acting directly on the arterial wall. In the destruction and dehydration of tissue, guanidine and histamine or similar substances may be set free.¹¹ In dogs, Hall, Ettinger and Banting¹² have produced hyaline degeneration and thrombosis of the coronary arteries with degeneration and infarction of the heart muscle by repeated injections of acetylcholine. However, they could not duplicate these results with histamine. It is significant that the most marked changes occurred in the older dogs. As we have already emphasized, postoperative occlusions also occur almost exclusively in patients 50 years of age or older. The second factor to be considered is the relation of infection to coronary occlusion, because of the presence of severe suppuration in many of our cases. While we concluded in the large series previously¹ mentioned that infection was too rare to be significant, it is possible that it played some part in the postoperative occlusions.

These considerations of the possible factors in operation leading to coronary artery occlusion are necessarily theoretical. It is probable that no one factor, but rather a combination of several, is sufficient to produce coronary occlusion in persons already susceptible because of long standing disease of the coronary artery. However, the relation of operation to coronary occlusion is of practical importance and, since a number of conditions associated with operation can be controlled, a study of these may throw light on the problem. It may lead to the formulation of criteria for operation in elderly persons and measures to be

employed during and after the surgical procedure. Such a study should include a comprehensive history and examination of the cardiovascular system, electrocardiograms and observations of the velocity of blood flow, blood volume, platelets, total protein and coagulability of the blood before and after operation. Particular attention should be given to the blood pressure, which should be recorded frequently during and immediately after operation. Coincidentally, minute anatomic studies are being made in our cases of postoperative and spontaneous coronary occlusion, with particular reference to the formation of the arterial occlusion. In the regard the relative importance of thrombosis on an atherosclerotic plaque and subintimal hemorrhage is being determined.

SUMMARY

Thirty-five proved attacks of coronary artery occlusion occurring after operation in the Mount Sinai Hospital during the years 1931 to 1937 were analyzed. Thirteen additional probable cases were excluded.

Previous coronary artery disease was probably present in every case. Two thirds of the patients were 60 years of age or older. Only four were under 50.

Surgical shock was present in 60 per cent of the cases.

Postoperative coronary artery occlusion presents a picture similar to pulmonary embolism, characterized by shock, dyspnea and cyanosis. Precordial pain is usually absent or is slight.

Sixty-six per cent of the patients died. In eight cases death was attributed directly to the occlusion, in the remainder it was associated with serious surgical complications.

Occlusion occurred in the first three days after operation in half the cases. Coronary occlusion appears extremely rarely in patients in the medical wards. The postoperative occlusions comprised 5 per cent of the total number of attacks in the hospital, an incidence which is significant.

The possible factors associated with the operation leading to coronary occlusion include surgical shock attended by a diminution in blood volume and a drop in blood pressure, tachycardia, dehydration and infection. Bed rest was not a factor.

In patients with coronary artery disease, operation may be followed by coronary occlusion. Therefore, patients over 45 should be thoroughly examined and when coronary sclerosis is present the question of surgical intervention and the choice of surgical procedure should be given due consideration.

125 East Seventy-Second Street

Benjamin Rush Eulogized by Two Presidents—Perhaps the most impressive tributes paid to Rush the man upon his death in 1813, came from two ex-Presidents, both of whom had numbered among his dearest friends. Even discounting the possible exaggeration arising from deeply stirred emotion, this characterization of Rush by John Adams retains a high degree of significance. As a man of science, letters, taste, sense, philosophy, patriotism, religion, morality, merit and usefulness taken all together, Rush has not left his equal in America nor that I know in the world. No less significant a personal tribute is that contained in a letter of Thomas Jefferson to Adams: "Another of our friends of seventy six is gone dear Sir, another of the co-signers of the Independence of our country. And a better man than Rush could not have left us more benevolent, more learned of finer genius or more forward." —Deutsch, Albert. *The Mentally Ill in America*. BASAL ANESTHESIA THE USE OF EVIPAL SOLUBLE BY RECTUM

ALFRED E. JONES, M.D.
CHICAGO

The term basal anesthesia has been used in the literature by several authors in at least three different senses. For the sake of clarity it seems desirable at the outset to differentiate these expressions:

1 Basal anesthesia may mean simple induction anesthesia, with prompt recourse to inhalation or regional anesthesia as soon as the patient has become unconscious. In this sense it is synonymous with basal hypnosis.

2 It may refer to a deeper sleep, carried to the point of complete surgical anesthesia and maintained during the early stages of a more or less prolonged intervention, but still frankly constituting an auxiliary and preliminary procedure, whose purpose it is to usher in smoothly the chief anesthetic agent under which the substantial part of the operation is to be performed. Here the inhalation anesthesia is still intended to be a definite part of the procedure and is more than terminal when the operation is one that cannot be hurried.

3 Basal anesthesia may mean a profound state of unconsciousness, ushered in by suitable premedication and pushed to a plateau of tolerance, which is held almost indefinitely as the backbone, so to speak, of the anesthesia but is finally supplemented by brief recourse to inhalation anesthesia when, in the surgeon's judgment, the limit of safety has been reached. Here the main work is done under the basal anesthetic, and the resort, in the terminal stages of the operation, to some inhalation anesthetic such as ethylene or ether is more or less incidental.

It is in this third sense that the German authors, who have written most on the subject, use the term, especially in connection with intravenous evipal soluble basal anesthesia. Thus Anschutz,¹ who in 1933 had already studied a collection of 6,400 operations under evipal soluble narcosis (known as evipan sodium narcosis to its German originators), expressed the opinion that "evipan is good as an induction or preliminary anesthetic but this is quite different from basal anesthesia." On the other hand, by way of contradistinction, he regarded pernocton, because of its long, slow elimination, as "not adapted to premedicamentous use but as excellent for basal narcosis, since it holds a plateau of tolerance for a long time." He added "Evipan is pharmacologically not a good basal anesthetic because it is too quickly decomposed. The supplementary anesthetic must predominate quite early. If full surgical anesthesia is accomplished with evipan, and then an inhalation anesthetic is used merely to complete the operation the drug becomes dangerous."

On the other hand, Coe² of Seattle uses the term basal anesthesia to mean "a state of unconsciousness of such degree that the patient is unaware of the events incident to his removal from his bed to the operating room and of the administration of the supplemental anesthesia. This also implies such a degree of amnesia that there is no subsequent memory of the operation."

In discussing the rectal use of evipal soluble as a basal anesthetic I shall use the term in Coe's sense. While it is perfectly true that evipal soluble is today being used in all these ways and also as a brief independent

anesthetic for minor surgery, as Widenhorn³ has recently pointed out, I am speaking here not of its independent use nor of its employment as the backbone of the anesthesia but always of its preliminary use immediately in advance of an inhalation or local anesthetic, to allay the anxiety of the patient, to accomplish the easy induction of general anesthesia and to promote better relaxation, while at the same time using only from one third to one half of the usual amount of ethylene, ether or other general anesthetic.

HISTORICAL

It is now almost five years since Weese⁴ in Germany engaged in the accurate study of the effects of evipan sodium, or evipal soluble, which, as the sodium salt of C-C-cyclohexenyl-N-methyl barbituric acid, Kroft and Taube had isolated in 1932 in their search for a new barbiturate that should lack in the field of anesthesia the disadvantages of the older barbiturates.

The introduction of evipal soluble as an intravenous anesthetic is therefore already an old story. Its use spread like wildfire in Germany and the extent to which it has now been adopted the world over is so vast that it defies exact figures. Veal and Hamilton⁵ wrote in 1936 that it had been used "perhaps in 200,000 cases." Gwathmey,⁶ earlier in the same year, said that it had been used intravenously "over 800,000 times in Europe," giving Killian⁷ as his authority. But meanwhile no less an authority than Baetzner⁸ with 2,000 evipan anesthetics to his own credit without a death, announced to the congress of surgeons held in Berlin in the fall of 1935 that the number of cases in which evipan had been used was estimated as already over one and a half million and that 550 original articles had been written on the subject, largely in Germany. The number of known deaths, Baetzner stated, according to the manufacturers, then stood at sixty. These were mostly due to "errors of dosage and misunderstanding of direction."

Baetzner, however, pointed out that the dosage is the alpha and omega of evipan anesthesia and that every patient is an individual in his degree of tolerance to this fascinating but capricious barbiturate. If by chance detoxification is for any reason hindered, as may happen in the case of an impaired liver or faulty circulation, a very slight degree of overdosage may kill through the accumulation of an excessive concentration in the blood, such as would be perfectly tolerated by some other individual without such functional impairment.

This relative uncertainty as to the dosage, combined with the uncontrollability of every intravenous anesthetic, once it has entered the blood, has proved at least disconcerting to those who have found in evipal soluble, in other respects, an ideal basal anesthetic. The smoothness of induction, the rapidity with which the patients fall into a quiet sleep, often even within the span of a minute, without struggle or excitement of any kind, provided there has been sedative premedication, the early muscular relaxation, the full and regular pulse, the prompt return to consciousness, but with a pleasant postoperative drowsiness that induces additional quiet sleep until the immediate postoperative pain

has abated and, finally, the absence of postoperative nausea and vomiting—all these are advantages of a high order that place intravenous evipal soluble in a class by itself in the forefront of basal anesthetics when it is in the hands of an anesthetist who is aware of the idiosyncrasies of his patients. But it is just this difficulty of dosage and the irrecoverability of the drug after it enters the blood that prevents intravenous evipal soluble from being the ideal anesthetic.

RECTAL EVIPAL SOLUBLE ANESTHESIA

In view of these considerations, the announcement by Gwathmey⁶ early in 1936 that he was using evipal soluble as a basal anesthetic by the rectal route with remarkable results was of the greatest interest. Like others, I had been using intravenous evipal soluble and my results had been gratifying, but always there had been that latent uncertainty of how the patient would react.

Gwathmey first tried the rectal method in the laboratory, using rabbits and dogs. Although rabbits were found not to be good animals for rectal experiments, he was able to prove even in these that with 5 mg of morphine per kilogram of body weight and 50 mg of evipal soluble per kilogram, seven of nine rabbits could be anesthetized, with no deaths. His experiments on dogs established conclusively that these could be anesthetized for forty minutes by rectal administration of a minimal dose of 40 mg of evipal soluble per kilogram of body weight in a 10 per cent aqueous solution. Larger doses produced longer anesthesia, with complete muscular relaxation occurring within three minutes, with no visible impairment of respiration or heart action. In one dog rectal administration of 175 mg per kilogram produced surgical anesthesia lasting seventeen hours.

From these experiments Gwathmey concluded that the margin of safety when evipal soluble is introduced into the rectum of dogs is very great, even when an injection of morphine, increasing the depressing action, has preceded it. He found that the therapeutic index (minimum lethal dose divided by anesthetic dose) is over 40 for rectal administration, as against 3.3 when administration is by the intravenous route. It was thus clear not only that its rectal use was safe but also that a very much longer anesthesia resulted, which is of great importance for major operations.

When Gwathmey published his report in 1936 he had made clinical use of the rectal method of administration of evipal soluble in more than 150 cases of the most various nature, using it only for preanesthetic medication and supplementing it with inhalation of ethylene and oxygen. He stated that the results were eminently satisfactory, there were no changes of any consequence in pulse, respiration or blood pressure, not even such moderate changes as have frequently been observed after intravenous administration. So far as I have been able to judge from a careful study of the literature, Gwathmey is the pioneer in this rectal use of evipal soluble. I have been able to find no other report of patients thus treated and placed on record.^{8a}

REPORT OF 518 CASES OF RECTAL EVIPAL ANESTHESIA

Encouraged by Gwathmey's results, we determined to give the method a thorough trial at the Michael Reese Hospital. As a result, I am able today to report

518 cases in which, during the last twelve months evipal soluble was used rectally, principally as a preliminary anesthetic to provide basal anesthesia before administration of ether, ethylene or local anesthesia. The cases represented a wide variety of surgical conditions encountered in general surgery, urologic, orthopedic and gynecologic surgery, many of a major nature as well as many cases in the minor class. In a certain number of cases in which only a fleeting anesthesia was required we have used evipal soluble alone, by rectum, as for example in the removal of stitches and drains in children, in the administration of drugs for excretion urography and in three cases for relief of pain in renal colic. It is worthy of mention that in excretion urography in children it has meant all the difference between a clear film of definite diagnostic value and a hazy or less roentgenogram.

These 518 cases fall roughly into four groups: (1) kidney, ureter and bladder conditions, 203, (2) general surgical, orthopedic and gynecologic, 176, (3) in children, for excretion urography, removal of stitches, drains and the like, 136, and (4) renal and ureteral colic, three cases.

DOSAGE

The dose is determined chiefly with reference to body weight as in intravenous administration, but on a different quantitative basis, the dose being larger for rectal use. Thus, for preanesthetic rectal administration the patient, if in good general condition, receives 0.2 cc. of a 10 per cent aqueous solution of evipal soluble for every pound of body weight (instead of 0.06 cc. as in intravenous administration), making a total of 30 cc. of the 10 per cent solution for a man weighing 150 pounds (68 Kg.) that is, a dose of 3 Gm of evipal soluble.

TECHNIC

Our technic, which is very simple, has been essentially that of Gwathmey. A preliminary enema of sodium bicarbonate solution is generally given two hours before the rectal administration of evipal solution. No soap-suds enema is required such as is given before oil-ether anesthesia by rectum. From forty to sixty minutes before the time for the evipal solution by rectum, morphine or dilaudid is injected hypodermically, thus producing a mental calm and freedom from agitation, which combination furnishes the foundation for a peaceful sleep of adequate duration and also prevents any reaction that might be offered to the rectal procedure.

The solution of evipal is prepared by dissolving 3 Gm of evipal soluble in 30 cc of distilled water, which is then drawn into a 30 cc glass syringe. A very small catheter is attached to the syringe, care being taken that its caliber is such as to fit the syringe exactly, so that there shall be no loss of the anesthetic solution through leakage.

The patient is placed on his left side in a comfortable position as for any ordinary enema, after which the catheter, well lubricated, is inserted for about 4 inches (10 cm) into the rectum. The entire contents of the syringe are then rapidly injected. The catheter is clamped and left in situ until the patient falls asleep, which usually occurs in from five to ten minutes, but occasionally in as little time as two minutes.

ADVANTAGES OF RECTAL ADMINISTRATION

The rectal injection of evipal soluble has the great advantage that it can safely be carried out by a trained nurse without the presence of a professional anesthetist. The relatively slower action of the anesthetic as it is gradually absorbed by the colonic mucosa

^{8a} Since this article was written two other articles on the same subject have been published:
Hogan Howard Am J Surg, November 1937
Harrison J H and Dumphy J E. New England J Med January 1938

assures safety that can never be absolute in an intravenous injection. Sudden accidents do not happen. There is never any dropping of the jaw to jeopardize the open airway.

The injection, usually given one-half hour before the time set for operation, is carried out in the quiet of the patient's own room, just where he will find himself on awaking after the operation is concluded. If the patient is a child, which is very often the case—since this method is particularly indicated in children—it is very simple to explain a procedure with which the child is already probably familiar without the psychic horror of a needle inserted in a vein. The earlier sedative, which can be given to a child by mouth, will have taken the edge off his fears, and cooperation will be easily enlisted.

As the evipal solution, freshly mixed, is entirely non-irritating, there is little tendency for the small amount of fluid to be expelled. Should there be any signs of spasm or straining during instillation, the syringe should be immediately lowered below the level of the rectum to remove pressure and permit some of the solution to flow back into the syringe and to allow any gas that may be present to pass out. At the close of the injection, pressure should be maintained over the anus for five minutes.

Absorption from the colon begins almost at once. When Gwathmey introduced his oil-ether colonic anesthesia he was able to detect ether being exhaled from the lungs within three minutes of the beginning of the procedure. The absorption of evipal is not less rapid and constant. It is not so active, however, as to prevent the washing out of the anesthetic if occasion should seem to demand it, in the early stages of introduction. If there should be any reason to suspect that anesthesia is becoming too deep in the first fifteen to twenty minutes following the injection, it is easily possible to siphon out the portion not yet absorbed, thus preventing any higher concentration of evipal in the blood. In none of our cases, however, have we had occasion to do this.

The quiet sleep that is prolonged for several hours after the operation is completed under ether or ethylene is evidence of the superiority of this method over the intravenous, in which, to accomplish the same duration and level of narcosis, one must keep on putting fractional doses of evipal into the blood stream, under the constant watchful eye of a skilful and experienced anesthetist, who must be ready at an instant's notice to administer pyridine betacarboxic acid diethylamide (coramin) or other cardiac and respiratory stimulant if the anesthesia becomes too deep. Gwathmey asserts that since evipal soluble by rectum affects only the sensory nerves and has no effect whatever on the heart, it is an unusually safe basal anesthetic. Not even when the amount administered far exceeded the standard dose of 0.2 cc per pound has he ever had to use either metrazol or carbon dioxide and oxygen.

We can absolutely confirm Gwathmey's experience. After long use of evipal soluble intravenously under a wide variety of conditions and in patients requiring the most varied kinds of surgical intervention, we do not hesitate to say that the results we are obtaining from the rectal use of evipal soluble are in no way inferior to those which we have attained by the intravenous method, and the safety provided by the rectal administration appears to us so incomparably great that we have come to regard it as actually superior to the earlier method, in which an injection made too rapidly might easily lead to an overdose.

RESULTS IN OUR SERIES OF 518 CASES

The results in all our cases have been most gratifying. In practically every case the patient fell into a quiet, restful sleep within five to ten minutes of the time the injection was given. There was complete relaxation, with deep rhythmic breathing and good heart action. The blood pressure dropped slightly in most cases but not more than a few millimeters. As a terminal or supplementary anesthetic we made use of ether or ethylene in the majority of cases. We found the circulatory and respiratory changes following rectal administration of evipal soluble to be practically nil compared with those following other preanesthetic drugs. In eleven cases (2.1 per cent) there has been marked confusion or delirium on waking. Most of these occurred early in our series, and they can properly be attributed to an idiosyncrasy to barbiturates which some patients manifest. This agitation can be materially lessened by making sure that the patient has had no other barbiturate by mouth or otherwise for at least twenty-four hours before the administration of the evipal soluble.

COMMENT

The use of some preanesthetic sedative is practically universal in present day surgery. It was realized not only that a smoother anesthesia could thus be produced, with great psychic advantage to the patient and better muscular relaxation for the benefit of the surgeon, but also that such preoperative medication would result in less inhalation anesthetic being required, since the drugs would reinforce one another. The presence of postoperative pain as a rule necessitates the use of some hypnotic or analgesic. It was a distinct step in advance, therefore, when surgeons began to give this sedative injection before instead of postponing it until after operation. Patients who would otherwise have been agitated with nervous fears were thus enabled to approach operation with perfect calmness.

To secure this state of mental relaxation, morphine, dilaudid, scopolamine, chloroform induction, evipal soluble intravenously and various older barbiturates, notably pernoston, sodium amytal and pentobarbital sodium, are all employed, and each has its adherents. A comparison of the relative efficiency of these agents may therefore be in order.

Morphine—No premedicament has had a longer history as an induction anesthetic than morphine, usually combined with atropine or scopolamine. The great weight of authority was with this alkaloid until the intravenous use of evipal soluble came on the scene and even since the latter's arrival morphine continues to enjoy the position of choice as a preliminary medicament for the induction of evipal anesthesia itself. Its use prolongs the anesthesia, prevents muscular spasm and completely abolishes restlessness through its action on the cerebral cortex. It produces a preoperative euphoria unequalled by any other agent, lessens excitement during induction, relaxes the muscles, diminishes liability to shock and lengthens the recovery period so that there is less postoperative discomfort or pain. But, on the other hand, morphine depresses the respiratory apparatus, blocks secretion, especially through the kidney function and, most of all, stimulates the vomiting center to such an extent that some patients actually prefer to accept postoperative pain.

Scopolamine (levo-rotatory)—This is hypnotic and antispasmodic in dosage of from $\frac{1}{100}$ to $\frac{1}{100}$ grain (0.3 to 0.6 mg). Like morphine, it depresses the cerebral cortex, the respiratory center, the heart action

and the reflexes. Its combination with morphine enhances these effects and tends to prevent a stage of excitement that may precede its sedative effect if it is given alone. While full amnesia is not invariably attained by this combination the sedative effect is very striking, making a subsequent nitrous oxide-oxygen anesthesia much more satisfactory. Just as with morphine alone, nausea tends to follow its use, and in certain cases scopolamine promotes a hemorrhagic tendency in incision of the skin and mucous membranes.

Dilaudid—This opium derivative, far superior to morphine in the opinion of many, meets the demands for an efficient preoperative sedative, offering the quickest and most intensive action, combined with a minimal effect on the gastro-intestinal tract and the least danger of habit formation. All psychic and motor excitation are reduced to a minimum before narcosis, and a quiet sleep may be expected within ten minutes at the least after intramuscular injection. Its use is cheaper than that of morphine, a lesser quantity is required and the amount of inhalation anesthetic necessary is greatly diminished. Gwathmey found that he obtained better results with rectal administration of evipal soluble when he substituted premedication with dilaudid for that with morphine. Postoperative nausea and vomiting have been entirely absent, in contrast with 16 per cent of patients being thus affected when morphine hydrochloride was used. Our own experience confirms these observations.

Chloroform—As an induction anesthetic chloroform has many serious disadvantages. While it is inhaled more easily than ether and is generally regarded as pleasanter to take, the sudden intake of an excessive concentration of chloroform stimulates the vagal center in the medulla to inhibit the heart's action. Acting as an irritant to the cardiac muscle, it sometimes leads to ventricular fibrillation. Collapse followed by resuscitation may again be followed by secondary collapse. Postoperative vomiting and headache are frequently late sequels to its use—the result of delayed poisoning, with symptoms of shock and not infrequently complications of the chest. As the induction stage is the most risky period with chloroform, many anesthetists who like it for a maintenance anesthesia will not use it for induction.

Barbiturates (exclusive of evipal)—The barbiturates came into use in 1903, when veronal led the way and was much used as a basal anesthetic to precede chloroform. Since then thirty barbiturates have been found, which have been used as hypnotics or basal anesthetics. Any barbiturate properly administered before anesthesia is capable of producing a mild surgical anesthesia, but most of them tend to produce subsequent headache, nausea and vomiting. The best known and most extensively used are sodium amytal (sodium isoamylethylbarbiturate), pernoston (the sodium salt of secondary butyl-beta-bromallylbarbituric acid) and pentobarbital sodium (sodium ethyl-1-methyl-butyl barbiturate). Any of these may be administered by mouth, vein or rectum. All have had their ardent adherents as preanesthetic agents, but all carry their dangers. When injected intravenously, the amount required to produce complete anesthesia is dangerously near the fatal dose. This is especially true of pernoston. The latter is pleasant to take and consciousness is lost fairly quickly, but the margin of safety is narrower than that of the other two barbiturates named. Sodium amytal, while effective, causes too great a drop in blood pressure if given too

rapidly and may bring on pulmonary edema and pneumonia if given in excessive dosage. The postoperative danger of the tongue falling back is considerable. Pentobarbital sodium is the most efficient hypnotic of the three, but it was pentobarbital sodium (nembutal) that led Lundy⁹ in 1931 to conclude that intravenous anesthesia by means of the barbiturates alone is not justified because of occasional untoward results. As a basal anesthetic, however, it provides a pleasant method of bridging the gap between consciousness and unconsciousness before general anesthesia. All these barbiturates decrease nausea to some degree, so that vomiting, if present, is slight and is seldom remembered.

In 1930 Fitch, Waters and Tatum,¹⁰ after prolonged laboratory and clinical research, reported "Amytal produced a much longer sleep than pernoston or nembutal. Occasionally excitement or delirium follows the use of all three drugs. The long period of detoxification and depression after administration of amytal and other long acting barbiturates constitutes a serious impairment of their value for surgical purposes. The more rapidly acting barbiturates furnish a distinct improvement and indicate possibilities and direction for further improvement." Thus was the way pointed toward evipal soluble.

Intravenous Evipal Soluble as a Basal Anesthetic—With the introduction of evipal soluble, the long awaited quick-acting and quick-receding basal anesthetic was realized. Though nonvolatile, it surpasses the volatile anesthetic agents in the rapidity of its detoxification and elimination. While it has a relatively short tolerance stage (from ten to twenty minutes) as compared with other barbiturates, this stage can be prolonged at will by giving fractional doses and repeating the administration as often as signs of returning consciousness appear, thus keeping the patient just within the limits of full anesthesia. This was done at first with the greatest possible caution, but today a constantly increasing number of anesthetists are pushing the use of evipal soluble as a complete anesthetic. I am concerned here with its use only as a basal anesthetic.

The rapidity with which the patient falls asleep is truly dramatic, he may stop talking in the middle of a sentence, and consciousness may be lost within fifteen to twenty-five seconds after injection is begun. His color does not change, his breathing is deep and rhythmic, his heart action is unaffected. A slight fall of blood pressure usually occurs, but this returns to its former point on recovery. No changes in blood chemistry occur, and there is no postoperative nausea. In some cases in which morphine premedication has been employed before the injection of evipal soluble, the vomiting that occurs is due to the former drug, not to the evipal.

But evipal soluble has the disadvantage of all intravenous drugs that, once injected, it cannot be recovered nor can its action be reversed. Its very speed is again such reversal, so that, in case of untoward effect, some cardiac and respiratory stimulant such as coramin or metrazol must be close at hand and immediately administered or the respiration and heart action may stop. In addition, as Dunphy and his associates¹¹ have recently emphasized, this inherent danger is increased by a greater

⁹ Lundy, J. S. Experience with Sodium Ethyl (1 Methyl) Barbiturate (Nembutal) in More Than 2,300 Cases. *S. Clin. N. A. America* 11: 909 (Aug.) 1931.

¹⁰ Fitch, R. H., Waters, R. M. and Tatum, A. L. Barbiturates as Hypnotics in Surgery. *Am. J. Surg.* 9: 110-114 (July) 1930.

individual variation in the effective dose. It follows, then, that certain patients are highly resistant to evipal soluble, while certain others are inordinately sensitive to it. The impossibility of recognizing these types in advance of administration is what constitutes the danger in its intravenous use. While the actual number of deaths attributable to this cause is small (sixty in perhaps one and one-half million cases), these fatalities must nevertheless be borne in mind and should serve as a warning when a choice is possible between the uncertainties of intravenous administration and the safety of the rectal use of evipal soluble.

CONTRAINDICATIONS

There are not many contraindications to the administration of evipal soluble by rectum. Just as is the case in its intravenous use, subjects known to have impaired liver function or myocardial degeneration are poor risks, since it is known that evipal soluble is detoxified in the liver, and a good circulation is required to carry it there as well as to remove its disintegrated components. Regardless of which organ does the eliminating of an anesthetic, its inactivation, as Weiss¹² well says, is always dependent on proper circulation. This, rather than the danger from direct action on the heart, is one of the main reasons why the use of non-volatile anesthetics is potentially dangerous when the individual tolerance is not known.

Anemic and weak persons should not be given evipal soluble, nor should those in a cachectic or septic condition. There are also grounds for withholding it from asthmatic patients, some of them having had attacks during its administration. It should also be denied to those subjects who have an abnormally low blood pressure and to those who have recently received other medication with barbiturates.

Beyond these obviously unsuitable groups there are no known contraindications to the rectal administration of evipal soluble.

CONCLUSIONS

1 The rectal administration of evipal soluble as a basal anesthetic has been found to be a practical and satisfactory method, eliminating certain dangers inherent in the intravenous use of this powerful barbiturate.

2 A report is made of 518 cases thus managed at the Michael Reese Hospital, representing a wide variety of different surgical conditions and operative procedures.

3 The technic is simple and requires no special training.

4 The administration can be carried out readily by any trained nurse without the presence of a professional anesthetist.

5 In no case did there occur any untoward symptom during operation, and in only 2 per cent of the cases did we observe any postoperative excitement.

6 The rectal method of administration has the advantage of producing a smooth basal anesthesia of extended duration, without the necessity of adding continued fractional doses, and it requires only from one third to one half of the amount of ether or ethylene for supplementary anesthesia.

7 The method offers all the advantages of intravenous evipal soluble without the disadvantages inherent to all intravenous anesthetics.

EMERGENCY TREATMENT IN ASTHMA (ASTHMATIC CRISIS)

G. L. WALDBOTT, M.D.

DETROIT

In the treatment of allergic asthma one is occasionally confronted with a serious emergency which has received little attention in recent textbooks. Its clinical picture is characterized by severe collapse with constant extreme dyspnea to the point of exhaustion. Some authors¹ refer to this condition in speaking of "status asthmaticus." Others have termed it "intractable asthma," thus indicating the inadequacy of the generally recognized methods of treatment. Fuchs² has recently called this condition "asthmatic crisis." This probably is the most appropriate term. It implies that this condition results either in death or in at least a temporary amelioration of the asthmatic condition.

Concerning its onset, Clarke states that the asthmatic crisis usually climaxes a chronic state of asthma, but it may also occur during a series of acute asthmatic attacks. On the basis of its occurrence in an individual who has previously been suffering from asthma, it is possible to draw a definite line distinguishing it from allergic shock. The latter condition would in every other respect be identical with the asthmatic crisis were it not possible to arise in any type of other sensitization besides asthma.

MECHANISM

Because of this close relationship,³ certain data obtained on the origin of allergic shock will aid in the understanding of the asthmatic crisis. The syndrome of allergic shock,⁴ it should be borne in mind, results, first, from extreme sensitivity, secondly, from an excessive amount of an antigen for the simultaneous absorption of several antigens to which sensitivity exists or, thirdly, from too sudden absorption (intravenous) of a dose of antigen which ordinarily would not produce shock. The manifestations of allergic shock depend largely on what organs have previously been affected.⁶ In the most common instance of allergic shock, namely, the "constitutional reaction" in a hay fever patient after an injection of an excessive dose of pollen extract, the skin and the upper respiratory tract are primarily subject to the allergic lesion, namely, the wheal, but practically any other organ may also be affected.¹ In patients with chronic asthma, however, the sudden influx of an excessive amount of injected antigen affects, primarily, the pulmonary tissue, causing severe asthma without the association of urticaria, nasal and conjunctival symptoms which are otherwise common. The same is true if the routes of entry of the antigen are other than by injection. Thus the asthmatic crisis can be considered as allergic shock in a patient whose "shock organ" has previously been the lungs, because he had been suffering from asthma.

Concerning the sources and the clinical manifestations of allergic shock induced by means other than injection

inhalation of helium gas as reported by Barach¹² and by Maytum and his associates¹⁹ may in some instances be explained by the displacement from the alveoli of air which is laden with harmful inhaled antigens and by its replacement with the dust-free gas. Therefore, its use is indicated even when no cyanosis is present.

In order to maintain the patient's nutritional state, intravenous injections of from 25 to 50 per cent solution of dextrose may be given. In addition to its caloric value, the osmotic effect of this hypertonic solution may aid in the removal of edematous fluid from the affected lungs. Mainly for the latter purpose, Gay²⁰ recently suggested the intravenous administration of 100 cc of 50 per cent sucrose to which 0.5 cc of 1,000 epinephrine solution was added. He observed instant cessation of extreme attacks in six asthmatic patients. Some of his patients had previously failed to respond when intravenous injections of dextrose and epinephrine were given individually.

Ascher and I have for several years used blood transfusions from either nonallergic persons or treated, symptom-free asthmatic patients. The principal purpose of these transfusions is their nutritional value. We considered it possible also that a certain immune effect might be established which could be compared to that of transfusions in certain infectious diseases. This conception is made more plausible through the recent experiments of Cooke and his associates²¹. They report the presence of protective or immune substances against specific antigens in allergic patients who had become symptom free. Whether or not these substances also exist in normal individuals is not indicated. Our own experiments along these lines have not as yet been conclusive. Clinically, however, transfusions from both normal and symptom free asthmatic patients were found very valuable. An intradermal skin test with the donor's blood and a preliminary small intravenous injection is first given in order to minimize the risk of untoward allergic reactions. (These might occur if the patient is sensitive to antigenic substances present in the blood of the donors²²). Between 200 and 400 cc of blood is then given in the usual manner. The patient's exhausted and debilitated state nearly always responds. With the precautions outlined I have not had any allergic reaction in more than forty transfusions given in cases of this type and in other cases of allergy.

4. *Hyposensitization*—Specific therapy has received very little attention in the literature on severe asthma. In my experience it is as indispensable in this emergency as in any other type of allergy. Waldbott and Ascher²³ have recently enlarged on the method of rapid hyposensitization. This is based on the observation that a patient with hay fever may obtain instant relief during the hay fever season following one or several injections of specific extract, provided the dose is large enough to produce a moderately sized local wheal and not too large to cause a generalized reaction. Guided by this principle of giving a sufficiently large amount and, at the same time, avoiding an overdose, this treatment can be made both effective and safe. The

antigens chosen should be those which were found to be the main causative agents of this attack, on the basis either of skin tests or of clinical experience. During the summer months, the respective pollen in the air at the time of the attack should always be considered as a potential cause²⁴. A scratch test should first be performed in order to gauge the patient's tolerance. In case of a strongly positive skin reaction no injection should be given, since repeated scratch tests with the antigen may accomplish a desensitizing effect. If the test is negative or slightly positive, an initial dose of a highly diluted extract (as low as from 1/10,000 to 1/1,000,000) is administered, preferably intracutaneously, and its effect carefully watched. If the injection does not produce a wheal, the dose can be worked up rapidly at intervals of one half to one hour until a local wheal appears at the site of the injection. From now on, future injections should be cautiously gauged and the intervals between them lengthened until the effect of the previous injection has well subsided. This may require from two to twelve hours and more. If properly gauged, the asthmatic attacks begin to clear up simultaneously with the development of a wheal, sometimes as dramatically as after an injection of epinephrine. If improvement does not ensue, other antigens should be chosen, because the one administered previously may not be one of the dominant agents in the production of this attack. During the course of the treatment one should constantly be watchful for an excessive local reaction at the site of injection and of an aggravation of the attack by the treatment. The injections should then be discontinued for several hours or for days until the flareup is thoroughly controlled. When the injections are started again, considerably smaller doses should be employed. If carried out with these precautions, rapid hyposensitization treatment constitutes the method of choice in this emergency.

BRONCHOSCOPIC TREATMENT

In addition to these methods of treatment, another means of therapy should be available to all those treating a patient with severe asthma, namely, bronchoscopy. It should be held in readiness in case the other measures fail. This treatment is often too indiscriminately used in asthma, especially if advocated for the administration of iodized oil²⁵. In the asthmatic crisis, however, especially when the emergency is extreme, the introduction of a bronchoscope into the lungs should be regarded as a life-saving measure. Its purpose is to remove the thick, tenacious mucus, which is such a grave source of danger to the asthmatic patient, and to dilate spastic bronchi.

In a review of the records of 1,431 allergic asthmatic patients, it was found that there were seventy-six who had been hospitalized on one or more occasions because of unusually severe attacks. In only eight cases did bronchoscopic treatment have to be resorted to. Extremely severe and "intractable" attacks promptly subsided on the removal of mucus from the bronchi in all but one case.

Mrs. R. L. B., aged 32, had been in a severe state of asthma for six weeks. She had given strongly positive cutaneous reactions to various antigens, especially grass pollen. During a two weeks stay at Grace Hospital she had shown practically no response to any of the aforementioned measures, including an attempt at hyposensitization. On bronchoscopy, considerable

spasm of the upper bronchial tree with but little edema of the mucosa and practically no secretion was noted in the bronchi. The day after the bronchoscopy she received 10 cc of blood intramuscularly from an asthmatic patient who had been symptom-free for more than one year. The attack promptly subsided within half an hour. However, it should be stated that the date of this treatment coincided with the termination of the grass pollen season.

Among these seventy-six cases, death occurred in only one case.

Mrs. R. S. had for eighteen years had severe allergic asthma which had been complicated by manifestations of cardiac insufficiency. During an aggravation of the attack evidence of cardiac failure and pulmonary edema developed which terminated in fatal pneumonia.

It may be of statistical interest that only three others out of the 1,431 patients with allergic asthma died while under my care and that drugs seemed to be responsible in every single instance. One patient (J. H.) died during a moderately severe attack a few seconds after he had administered to himself 1 cc of epinephrine. There was blood at the site of injection and the typical blanching effect on the skin was not present, indicating that a vein may have been punctured and the drug thus had been injected intravenously. Another chronic asthmatic patient (J. T.) was said to have taken a "patent medicine" containing coal tar products for a headache at a time when he had been entirely free from asthma. Within a few minutes severe shock, dyspnea, cyanosis and convulsions developed, followed immediately by death. The third patient (Mrs. L. S.) died in some unexplained manner, after having taken a hypnotic during the course of a light attack of asthma. She appeared to be in a natural sleep, which gradually turned into a comatose state from which she could not be aroused. Death occurred two hours after she took the hypnotic. No wheezing had been noticeable before her death.

SUMMARY

1. The "asthmatic crisis" represents either a sudden aggravation or the climax of a progressive state of asthma. It constitutes a grave emergency.

2. The following therapeutic principles are suggested:

(a) Extreme caution should be used in the introduction into the system of antigens that might aggravate the condition, particularly drugs.

(b) Such measures of elimination as are usually emphasized in the treatment of allergic disease should be carried out. Hospitalization is of great assistance in accomplishing this. In addition, withdrawal of epinephrine and similar drugs that have been given before is advisable.

(c) Symptomatic relief can be accomplished by measures which secure rest and relaxation, allay cough, control existing cyanosis and aid in the maintenance of the patient's nutritional state.

(d) Specific hypsensitization with antigenic extracts that are considered the chief source of the attack should be employed as the method of choice.

3. Among seventy-six cases thus treated, one death occurred and eight patients were not benefited until bronchoscopy was resorted to. In seven of the eight cases the removal of thick tenacious mucus from the bronchial tree and an attempt at mechanical dilation of the bronchi resulted in prompt cessation of the emergency.

THE LOP EAR

DONALD W. MACCOLLUM, M.D.

Instructor in Surgery, Harvard University Medical School, Associate Visiting Surgeon, the Children's Hospital

BOSTON

The majority of articles on the malformations of the external ear have been published in European journals and comparatively few are in the English language. Most of these papers are limited to a report of an isolated case. Still more rare is the paper that deals with the ear in which all of the components are present but which are shaped so that the ear protrudes abnormally from the head. This deformity is commonly designated as a "lop ear" or "bat ear." The present article calls attention to this abnormality with especial emphasis on the explanation of the embryologic development and the surgical correction.

FORMATION

The external ear arises from six distinct tubercles and a ridge of tissue, all of which are grouped around the dorsal limit of the first branchial groove, which in turn gives rise to the external auditory canal. Three of these primordia are derived from the first branchial arch and four from the second. Fusion of these tubercles takes place in a regular sequence, so that in the completed ear the antitragus and the anterior curve of the helix are derived from the three tubercles of the first arch, and the remainder of the helix, antihelix, tragus and lobule from the three tubercles and the ridge of the second arch. Any one or more of the several primordia may fail to develop, resulting in a microtia with or without an atresia of the external auditory canal. Occasionally the elements of the ear may be completely formed but give the appearance of having been crumpled or crushed against the head. The latter deformities may be due either to faulty fusion of the tubercles or to some abnormal intra-uterine pressure.

During the third month of fetal life the ridge which is to form the helix grows more rapidly than any other portion of the ear, so that it projects forward and covers the three primordia of the second arch. Normally as the other components develop, the helix is gradually pushed upward and backward to form the outermost border of the ear. However, if there is a delay in development during this third month of fetal life the helix will remain in this forward position and continue its growth in a direction that is at a right angle rather than at a tangent to the head. The curved ridge of the antihelix does not develop so that the scapha may be regarded either as absent or as continuous with the curvature of the concha. This ear becomes the true lop ear.

As the infant develops, the conchal portion of the cartilage which at birth had an abnormal forward curvature continues to grow so that this forward curvature becomes even more pronounced. For this reason lop ears that are not noticeably abnormal at birth become more and more prominent during infancy and early childhood. This deformity is therefore often considered to be an acquired one rather than one of congenital origin and the blame is wrongly placed on the nurse or the mother who has allowed the ears to protrude beneath a cap or bonnet or has allowed the baby to sleep with the ears folded forward.

From the Surgical Service of the Children's Hospital and the Department of Surgery, Harvard University Medical School.

INCIDENCE

In comparison with many congenital anomalies, malformations of the external ear occur infrequently and are seldom seen repeatedly in the same family tree. During the twenty year period from Jan 1, 1918, to Jan 1, 1938, 108,744 children were admitted to the

Fig 1 (case 1)—Both ears are symmetrically prominent

Children's Hospital. Of this number only forty-six patients were treated for malformations of the ear and of these forty-six, only twenty-one had lop ears. In interpreting these figures it must be remembered that these anomalies exist much more commonly but are of such a nature that their correction is not considered important. It is interesting to note that all but two patients with lop ears were children of Irish extraction. This series is too small to justify any definite conclusion with regard to nationalities but it is a suggestive point since the racial distribution of patients treated at the Children's Hospital is far different from the percentage that occurs in this series.

In the group of twenty-one patients with lop ears there were sixteen boys and five girls. The deformity in the female becomes of less importance because it

Fig 2 (case 1)—Result six weeks after operation

may usually be hidden by a proper coiffure. In the male, however, it is liable to become a source of great embarrassment at an age when it may result in a permanent change in character. For this reason some attempt at correction should be made before the boy begins to associate with children of his age, who may be tactlessly cruel about the size and shape of his ears.

TREATMENT

On the faulty hypothesis that this is an acquired condition, attempts to correct the deformity have frequently involved fixation of the ear in its normal position by means of adhesive strapping, elastic cap, ear muffs or other mechanical appliances. In the series of twenty-one cases every patient seeking correction of a lop ear at the Children's Hospital gave a history of long continued trials with these mechanical restrainers. A failure was reported in every case in which these palliative measures were used.

It must again be emphasized that the causation of the lop ear is a congenital overgrowth of the conchal cartilage and a lack of the formation of the antihelix and scapha. It therefore follows that, in order to effect a restoration of the ear to its normal contour, the excessive cartilage must be reduced in size and reshaped so that the ear will lie back in its normal alignment with the head. The mechanical appliances may be of some aid in holding the ear back after its surgical correction, but they cannot be expected to bend the excess cartilage of the true lop ear permanently.

Fig 3 (case 2)—Marked protuberance of both ears

Many operative procedures have been outlined for the correction of the lop ear but in my opinion there are only three methods that meet the fundamental requisites for a satisfactory repair. These requisites are that 1 The angle formed between the ear and the mastoid region must be reduced to at least 30 degrees. 2 The convolutions of the cartilages must be shaped to form an antihelix and a scapha, both of which are absent in the lop ear. 3 The skin incision must be hidden behind the ear so that it is not readily noticeable.

FIRST METHOD

In correcting a lop ear the surgeon must plan to make the curvature of the antihelix less acute and the scapha slightly wider than in the normal ear. For the purposes of orientation the position of the planned antihelix is first marked off on the anterior surface with sterile Bonney's blue paint. Along this line, punctures are made through the entire ear with a needle carrying the paint so that the curvature of the new antihelix will be projected as a line of dots in the skin on the back of the auricle. These dots will then outline one side of an ellipse. The remainder of the ellipse is marked off so that one half of it lies on the posterior surface of the auricle and the other half over the mastoid region. Procaine hydrochloride and epinephrine are injected into the skin over the iron a

1 Components of Bonney's blue paint are brilliant green 10, crystal violet 87 Gm. 90 per cent alcohol 10 ounces distilled water 5 ounces.

back of the ear so as to facilitate the dissection of the cartilage and to prevent excessive bleeding. The ellipse of skin, previously outlined on the posterior surface is now removed. An incision is next made through the cartilage along the line demarcated by the ink dots previously produced by the perforating needle. Great care should be taken to avoid buttonholing the skin on the anterior surface. Through this incision the cartilage is then freed carefully from the skin on the anterior surface so that the edge of the outer portion of cartilage can be inserted under the edge of the proximal portion. The cut edge of the inner or proximal cartilage will then form the ridge of the new antihelix. As the two parts of the cartilage slide over each other it is found that the ear will begin to assume a normal position. In most cases the outer or distal cartilaginous plate, which is now to form the structural foundation of the scapha will be too wide. For this reason a sickle or crescent shaped portion of this outer cartilage must be removed before the cartilaginous convolutions simulate a normal appearance. It follows that the ear which protrudes markedly will require the excision of a wider strip of cartilage than one that is less prominent. When a satisfactory correction has been obtained, the two layers of cartilage are sutured to each other by interrupted sutures of

dressing none of these difficulties should arise. A dressing with identical pressure is then reapplied until the eighth or ninth day. After this time the patient is allowed to wear a pair of soft cotton pads held in place with elastic ear muffs. During the day when he is under close surveillance these ear muffs may be removed, but during the night or when at play they should be worn to protect the ear against sudden trauma.

Fig 4 (case 2)—Result one month after surgical correction. This patient also has a facial asymmetry not related to the deformity of the ears.

0000 chromic catgut. To insure their anchorage to the head, both are sutured as a layer to the postauricular fascia of the scalp. This brings the skin edges together so that they may be closed with a continuous subcuticular stitch of 0000 plain catgut.

The suture line is then painted with varnish² and a meshed tape applied. Pressure now must be applied to keep blood from collecting between the undermined skin and the underlying cartilage. To insure this each concavity on the anterior surface is packed with fine gauze that has been cut to the desired shape. These packs are held in place with an elastic net (Elastonette) over which are placed a knit skull cap, elastic adhesive (Elastoplast) and an elastic crape bandage (Vic or Ace). It is important that these bandages exert enough pressure to control all the oozing but not enough to endanger the viability of either the skin or the cartilage. The first dressing is removed on the third or fourth day for inspection of the color of the ear. If the procedure has been done with gentleness and if the skin has not been undermined too extensively, the ear should be of normal color. If there are any areas which are dusky or blue the ear must be examined for hematoma. If a hematoma has formed it must be expressed completely to avoid a slough of the skin overlying it. If the hematoma is incompletely expressed the result on healing will be a thickened, unightly cauliflower ear. If the ear remains blue even after the hematoma has been removed hot packs are advisable to stimulate the return of the normal circulation. With proper technique and a proper

Fig 5 (case 3)—Ears protruding beyond a right angle from the head.

At the end of a month the use of these pads may be discontinued and the result at that time may be considered as permanent.

This method of repair is applicable for all types of lop ears, but it is particularly indicated for those in which the conchal cartilage is more prominent than the rest of the ear. It has the obvious disadvantage of obliterating to a certain degree the normal postauricular sulcus. If the ear curls forward beyond a right angle from the head, this method of repair will necessarily result in a very shallow postauricular sulcus. For the latter case the second method is better chosen.

THE SECOND METHOD

The same preparation of the ear and marking of the curve of the new antihelix is to be followed as that outlined for the first method. The ear is similarly injected with procaine and epinephrine to aid in the dissection of the cartilage. In this repair a posterior incision is made through the skin and through

Fig 6 (case 3)—Result four weeks after operation.

the cartilage in the line marked by the ink of the perforating needle. An ellipse of skin is not removed in this repair. After the cartilage has been freed from the anterior skin the two cut cartilaginous edges are turned to point anteriorly. This places the distal and proximal portions of the cartilage back to back. They are held in this position with horizontal mattress stitches of white Deknatel silk. The use of black silk is to be avoided because later it may show through the thin skin on the anterior

² Component of the varnish are colophony 3 drachms, corn oil 4 drachms, turpentine 1 drachm, rosin 1 drachm, and benzoin 1 drachm.

surface The use of catgut is also undesirable because of the possibility of a reaction to the suture in the region of the knot with a resultant loss of the tension on the suture When the cartilages are sewn in this buckled position the conchal portion of the ear may be too prominent, so that it may project too far beyond the helix when the patient is viewed from the front If this occurs, narrow strips may be shaved from the rim of the proximal portion of the cartilage until the desired height is produced When the ear has been buckled back into the corrected position it will be found that the edges of the skin are approximated and are easily closed with a continuous subcuticular stitch of 0000 plain catgut A dressing similar to that described in the first method is then applied

This repair is applicable for the ear with a prominent pinna but without marked enlargement of the conchal cartilage It is slightly more difficult to match the position of the two ears with this method because the cartilage of one ear may buckle more readily than that of the other and thus produce an asymmetric result This method has one real advantage of retaining the postaural sulcus Occasionally this sulcus becomes too deep and is therefore unsightly This happens in the ear that is abnormally large in proportion to the other features and is best repaired by the third method

THIRD METHOD

The third method combines features of both methods 1 and 2 An ellipse of skin is removed as in method 1 but it is about half the width of that which would ordinarily be advocated for method 1 The cartilage is also excised as in method 1 but the shape of the piece removed is more pear shaped than crescentic, the widest portion being at the base of the conchal portion of the ear The edges of the remaining cartilage are then approximated back to back as in method 2 After this line of sutures is placed, the proximal portion of the cartilage is sewn to the galea of the scalp in the area made by the removal of the ellipse of skin Then the skin is closed in the fashion used in both previously described methods

The advantages of method 3 are that 1 The postaural sulcus is retained but is not as deep as in the second method, owing to the removal of the narrow ellipse of skin 2 The antihelix becomes smooth and cordlike in contradistinction to the sharper ridge formed in methods 1 and 2 This is due to the fibrous tissue, which fills in under the excess skin on the anterior surface which previously overlay the portion of the cartilage that was removed 3 With this repair the ear is in a potentially more secure position than it was in method 2 because of the added line of sutures holding the proximal cartilage to the head 4 The size of the entire ear is reduced

CONCLUSIONS

1 The malformations known as "lop or bat ears" are congenital in origin

2 True lop ears warrant plastic repair in childhood before the patient suffers embarrassment from a deformity which is so readily correctable

3 Three methods of plastic correction of this anomaly have been developed The principles are based on experiences with twenty-one patients who have been treated for this deformity in the Children's Hospital of Boston

300 Longwood Avenue

Medical Schools Guard Truth—Every medical school is a guardian for the future of truth What can be done to help those who come after us to acquire that balanced judgment by which alone such errors can be avoided? Is the present system of medical education entirely free from blame in the matter? I trow not—Langdon-Brown Walter The Dead Hand in Medical Science, *Lancet* 1 280 (Jan 29) 1938

OBESITY IN THE ADOLESCENT CURED WITHOUT INJECTIONS

HORACE GRAY, M.D.

SAN FRANCISCO

Obesity during the pubertal period usually raises the diagnostic question of adiposogenital dystrophy, based presumably on deficiency or at least disorder of gonadal or pituitary or thyroid or of a combination Definite diagnosis is often difficult in boys, and only boys are considered in this paper, the main reason is that the fat deposit above the symphysis pubis masks the size of the external genitalia

INCIDENCE

The frequency of occurrence in boys of high school age was estimated by Shapiro¹ in 1929 as 26 per cent and by Taylor and Schaefer² in 1937 as 23 per cent

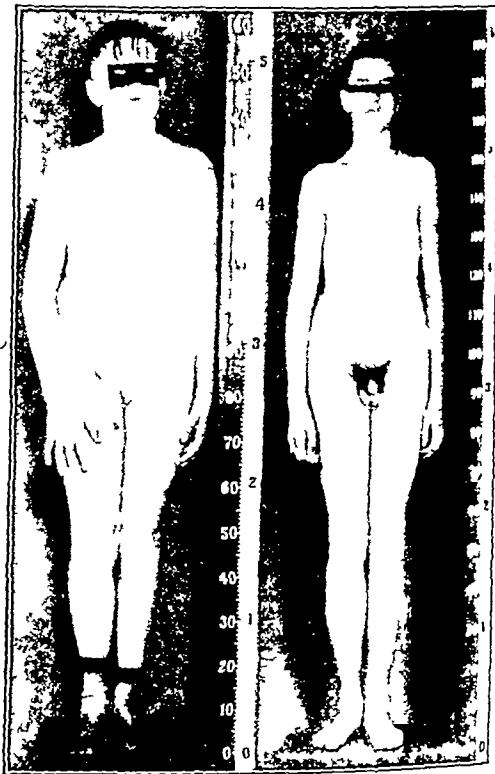

Fig 1—Patient 1 before and after treatment In the illustrations the appearance before treatment is given at the left, the appearance after treatment at the right

Economic advantages may increase the frequency, for Gray and Ayres³ in 1931, working in private school, found higher rates, which may be reviewed In order to be extremely conservative, they first discarded only those who appeared definitely outside the limits of normal, judged not merely by fat but by the medical appearance or history or both, of these there were eighteen

chosen, that marked obesity is more frequent than reported by the authors cited, this is clear from table 3

ENDOCRINE TREATMENT

Recent literature on reduction treatment in fat boys with more or less definite secondary sex backwardness, by injections of pituitary or testicular extract, will undoubtedly lead to frequent administration of these substances. In some cases this is a promising and

TABLE 3—Frequency of Overweights
(Condensed from Table 2)

| Criterion | Percentage of All Boys 11 to 19 Years | Percentage of Boys 12 to 19 Years |
|------------------------|---------------------------------------|-----------------------------------|
| 30% or more overweight | 27 | 30 |
| 25% or more overweight | 42 | 44 |
| 20% or more overweight | 70 | 73 |

desirable procedure. In all cases, however, the physician may be invited to consider: 1. That such extracts may, after wider use, prove to have some deleterious by-effects, so that their use should not be indiscriminate

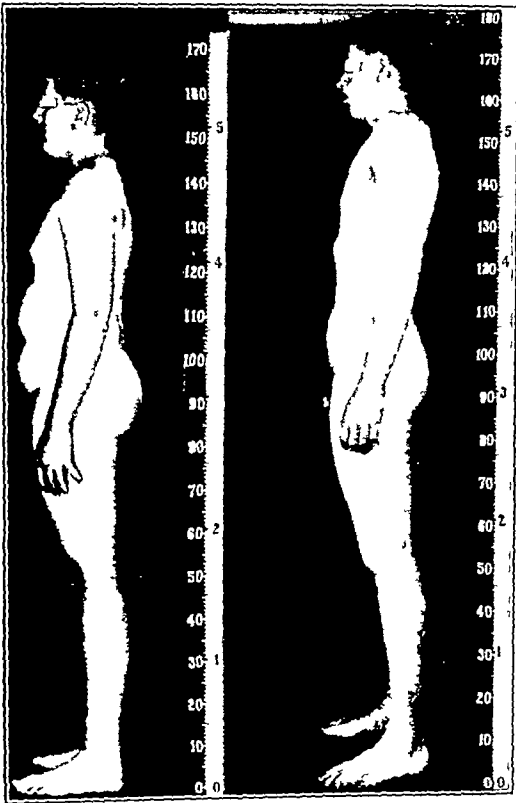

Fig. 4—Side view of patient 2 before and after treatment

2. That successful reductions following endocrine injections may be due less to the medication than to Mother Nature. We have long felt that such spontaneous reductions of weight during adolescence are commoner than is appreciated, we know no figures as to the frequency of such encouraging outcomes relative to the frequency of persisting disorder but we can now report two examples, fortified by "before and after" photographs and rather thorough studies of build. The anthropologic items measured were over a dozen, together with a somewhat larger number of indexes derived from the absolute measurements. Description of the items, landmarks and other aspects of technique have been reported elsewhere.² The interpretation of such a set of measurements after plotting on a profile

chart has been used in the past by others, was further described and illustrated by eighteen examples in the book referred to, and was similarly applied to our patients. In this paper, however, these extensive measurements and charts will not be reproduced, but only a brief selection of the more pertinent.

In order to clarify the significance of the figures about to be reported, the percentile has been calculated for many of the items for the individual with respect to a hundred normal persons of the same age, for example, let us take the stature of the first patient, 1,643 mm at the age of 12, this is 139 mm taller than the average for private school boys aged 12, dividing this by 67.4 mm, the standard deviation, we find his deviation from the average to be 2.06 SD or 2.06 times the standard deviation, and looking up this value in the probability table, we see that ninety-eight out of 100 boys of his age would be smaller than he, therefore we say he is in the 98 percentile rank. The two case histories follow.

DIET TREATMENT

Treatment was begun by our usual obesity diet of carbohydrate 80, protein 60, fat 40 Gm, namely, a bread and flour free regimen but including milk and vitamins. The food was not weighed by either of the patients. As soon as they had shown cooperation in facing the restrictions, the diet was increased, mainly to give a protein intake of about 1.5 Gm per kilogram of body weight normal for the patient's age and height.

CASE 1, History.—J. C. M. was referred by Dr. Donald Marshall. The family history shows that the parents and the grandparents were all born in the United States, of northwestern European ancestry, and were correspondingly large.

The patient's birth weight was 3,860 Gm (8½ pounds), i. e., a big baby. Examination showed an orchidopexy scar, uric acid and blood normal, blood pressure 115 systolic, 75 diastolic, and basal metabolic rate —16 per cent.

TABLE 4—Family History of Patient 1

| | | |
|-----------------------|-----------------------|--------------------|
| Father | 1 900 mm (6 ft 3 in.) | 207 pounds |
| Mother | 1 625 mm (5 ft 4 in.) | 130 pounds |
| Father's father | 1 880 mm (6 ft 2 in.) | 132 pounds |
| Father's mother | 1 753 mm (5 ft 9 in.) | 166 pounds |
| Mother's father | 1 829 mm (6 ft 0 in.) | 192 pounds |
| Mother's mother | 1 575 mm (5 ft 2 in.) | 151 pounds |
| Sister M. at 24 years | 1 714 mm = 98 rank | 60.8 kg = 137 rank |
| Sister D. at 23 years | 1 613 mm = 73 rank | 51.6 kg = 51C rank |
| Sister J. at 20 years | 1 598 mm = 84 rank | 51.7 kg = 54C rank |

TABLE 5—Measurements in Case 1 Before and After Treatment

| | Before | After |
|--------------|-------------------------------|-------------------------------|
| Age | Age 12.3 years | Age 16.2 years |
| Date | May 27, 1932 | April 2, 1934 |
| Weight | 56.8 kg (125 lbs) = 99 rank | 71.2 kg (157 lbs) = 85 rank |
| Stature | 1 643 mm (64.7 in.) = 98 rank | 1 857 mm (73.1 in.) = 97 rank |
| Bicristal | 280 mm = 99 rank | 309 mm = 97 rank |
| Sitting/S | 105.5% = 60 rank | 104.7% = 60 rank |
| W/S in kg/mm | 34.6% = 98 rank | 38.4% = 98 rank |

Build.—The illustrations tell the story. Both boys were tall, long legged (i. e., rather eunuchoid), and fat both with regard to age and with regard also to height.

The improvement in slenderization is most clearly shown by the weight/stature index as converted in terms of percentile rank, whereas "before" the patient was fatter for his height than 98 per cent of boys of his age, "after" the period of treatment he was fatter than only 76 per cent, that is, 24 per cent of boys of his age would be as fat as he.

CASE 2.—History.—W. B., of old American stock, 3,118 Gm (6 pounds 14 ounces) at birth, i. e., he was normal. His father, mother and one sister were normal in build.

Physical examination was negative. Urine and blood were normal. The basal metabolic rate was 13 per cent. The dextrose tolerance test gave the following readings: fasting 91 mg, one hour 177 mg, two hours 121 mg, 4 hours 120 mg, and

TABLE 6—Measurements in Case 2 Before and After Treatment

| | Before | | After |
|----------|------------------------------|--|-------------------------|
| Age | 14 3 years | | 19 3 years |
| Date | May 20 1932 | | May 8 1937 |
| Weight | 78 1 Kg (172 lbs) = 99 rank | | 79 1 Kg (174 lbs) = 94 |
| Stature | 1 720 mm (67 8 in) = 89 rank | | 1 836 mm (73 1 in) = 95 |
| Bierstäl | 294 mm = 93 rank | | 299 mm = 93 |
| Si/S | 50 6% = 65 rank | | 51 8% = 87 |
| W/S | 45 4% = 99 rank | | 42 6% = 91 |

no glycosuria. Bone age was normal. The sella was normal. The diet consisted of carbohydrate 125 Gm, protein 70 Gm, fat 70 Gm.

Build—He was like the other patient: tall, eunuchoid and fat.

SUMMARY

Two boys with obesity, genital hypoplasia, marked tallness and eunuchoid legs were observed for four years (from 12 to 16) and for five years (age 14 to 19), with diet but no endocrine injections. During observation their builds became sufficiently normal to eliminate any question of the need of added hormone. Measurements are given, but the improvements are more strikingly and simply manifest by photography.

THE ACTION OF HYPOGLYCEMIA ON THE CENTRAL NERVOUS SYSTEM

AND THE PROBLEM OF SCHIZOPHRENIA FROM THE PHYSIOLOGIC POINT OF VIEW

ERNST GELLHORN, M.D., PH.D.
CHICAGO

It is known that the anoxic and the hypoglycemic syndrome are similar (Kleitman and Magnus,¹ Olmsted and his collaborators²), but only recent work has shown that the two conditions are related in the essential physiologic mechanism involved. Holmes³ and Wortis⁴ have shown that the oxidation rate of brain tissue decreases with decreasing sugar concentration in the suspension fluid. Myerson and his collaborators⁵ found that the oxygen and sugar uptake by the brain are reduced in hypoglycemia.

In order to substantiate the anoxia theory of insulin convulsions and to extend it to the preconvulsive state, a series of experiments was carried out which may be briefly reported.

1. Gellhorn and Yesnick⁶ showed in narcotized dogs that the blood pressure response accompanying

a rise in intracranial pressure up to the blood pressure level is greatly increased in anoxia. An almost identical response could be obtained by substituting hypoglycemia for the inhalation of low oxygen.

2. Glickman and Gellhorn⁷ carried out numerous experiments on rats which were temporarily subjected to a relatively mild degree of anoxia (low pressure chamber). It was found that after a standard dose of insulin the insulin convulsions occur much earlier and are more severe than in control experiments carried out at normal barometric pressure.

3. Ingraham, Moldavsky and Gellhorn⁸ found in narcotized dogs that the blood pressure rise resulting from the inhalation of low oxygen is greatly increased during hypoglycemia. The inhalation of 6.2 per cent oxygen for from two to three minutes, which at a blood sugar level of about 100 mg per hundred cubic centimeters either does not alter the blood pressure or produces only a slight rise of a few millimeters of mercury, may at a blood sugar level of 40 mg per hundred cubic centimeters produce a rise of 80 or 100 mm of mercury. At the same time Cheyne-Stokes breathing may be observed. The reaction is reversible on the injection of dextrose. Fructose is less effective and galactose is unsuited to restore the original blood pressure reaction to low oxygen. The reaction is due to the lowering of the blood sugar by insulin and not to other changes in the blood.

From these experiments and the literature cited the following conclusions may be drawn:

1. Hypoglycemia acts on the central nervous system in a way similar to that of oxygen deficiency. In both instances the rate of oxidation is reduced.

2. The sensitivity of the central nervous system to oxygen deficiency is greatly increased in hypoglycemia.

3. The combination of hypoglycemia plus oxygen deficiency induced by insulin and the inhalation of an oxygen deficient gas mixture produces a more effective stimulation of the sympathetic nervous system measured by the blood pressure response than even the inhalation of pure nitrogen.

It seems reasonable to apply the physiologic principles elucidated in the foregoing experiments to the clinical problem presented by schizophrenic patients. It is to be expected that insulin improves schizophrenic patients by the same mechanisms which are called into play in the animal experiments that have been described, i.e., (1) by reduction in the oxidation rate in the central nervous system and (2) by the stimulation of the sympathetic centers resulting from the diminution of the oxidative metabolism.

Space does not permit of a detailed discussion of the reasons which induced various authors to use different remedies for the treatment of schizophrenia. It may suffice to state that insulin,⁹ metrazol,¹⁰ the prolonged narcosis treatment,¹¹ the injection of sodium cyanide,

the inhalation of from 30 to 40 per cent carbon dioxide¹² and, finally, the administration of cocaine have been introduced into psychiatry for various clinical and psychologic reasons. In no case was an attempt made to understand the physiologic mechanism involved. A study of the literature and my own experiments on metiazol indicate, however, that the various drugs mentioned have a very similar action on the central nervous system. Metiazol is a highly effective stimulant of the sympathetic system even under conditions in which the convulsions are suppressed (curare¹³). The narcosis treatment involves a reduction in the oxidation rate of the brain¹⁴ and is not infrequently accompanied by signs of sympathetic discharge at the end of the treatment¹⁵. Sodium cyanide and the inhalation of 30 or 40 per cent of carbon dioxide greatly interfere with the oxidative metabolism of the brain and stimulate the sympathetic system. And, finally, cocaine, which has been used occasionally with some success, is a typical stimulant of the sympathetic centers. From this it may be concluded that various treatments used in schizophrenia are effective because they produce, by a profound alteration in the metabolism of the central nervous system a sufficiently strong and lasting excitation of the sympathetic nervous system and thereby bring about a far reaching reorganization of all mental processes.

If the interpretation given is correct, it is to be expected that schizophrenia is characterized by a deficiency of the autonomic nervous system and particularly of its sympathetic division. Experiments of Pfister¹⁶ on schizophrenic patients, and direct clinical observations (Singer¹⁷) seem to confirm this conclusion. I therefore come to the conclusion that schizophrenia involves a hypofunction of the sympathetic system and that improvement or cure may be brought about by a sufficient stimulation of the sympathetic centers. My own experiments, with a combination of hypoglycemia and inhalation of an oxygen deficient gas mixture, have shown that a very marked stimulation of the sympathetic nervous system may be produced in this way. The reduction in oxidative metabolism achieved is far greater in the brain than in other organs, since the brain oxidizes carbohydrates almost exclusively, whereas other organs can oxidize noncarbohydrate material when the blood sugar concentration is low¹⁸.

It will be the task of clinical experimentation to determine the most favorable conditions for the practical application of this combination. It may be stated, however, that the effect of this or any other procedure, according to this theory, depends on the degree and duration of the excitation of the sympathetic centers. Whether the alteration in oxidative metabolism is of specific importance remains to be seen. At any rate, if the interpretation given is correct, the therapy of

schizophrenia will be guided in the future not by empiric observations but by a definite physiologic theory and by experiments designed to find the most suitable and effective procedure for the excitation of the sympathetic centers. It seems that physiologic research has opened up a new and promising road to combat not only schizophrenia but also other psychoses such as the manic-depressive psychoses, in which vegetative disturbances are very prominent. Work along these lines is in progress.

A TRICHINOSIS EPIDEMIC OF SIXTY-FOUR CASES

THOMAS L FERENBAUGH, MD

Colonel Medical Corps, United States Army Surgeon Station Hospital
FORT ETHAN ALLEN, VT

LEO SEGAL, MD

1st Lieutenant Medical Reserve Corps United States Army
BURLINGTON, VT

AND

H A SCHULZE, MD

1st Lieutenant Medical Reserve Corps United States Army
Surgeon Camp Charles M Smith
WATERBURY, VT

An epidemic of trichinosis occurred in the 1136th Company Civilian Conservation Corps at Camp Charles M Smith, Waterbury, Vt, during October 1937. Forty-four patients were admitted to the Station Hospital, Fort Ethan Allen, Vt, for treatment, after a variable period of observation in the camp dispensary at Waterbury.

The first patient, enrollee A, was admitted to the camp dispensary on October 30, complaining of head ache, chills and general malaise, acute coryza, severe sore throat, swollen and painful eyes and muscular soreness. He was observed at the camp dispensary from October 30 until November 5, when he was transferred to the Station Hospital, with a diagnosis of moderately severe sinusitis, frontal, acute, suppurative and bilateral, the cause of which was undetermined.

On his admission to the Station Hospital his temperature was 103.2 F. There was edema of the upper eyelids and suborbital edema to such an extent that the patient's face looked swollen. The muscles of his extremities and back were painful to pressure, and he complained of a stiff, painful neck. He had slight sore throat and stated that he had had difficulty in swallowing fluids for the past three days. He said that his illness began about October 27. He gave a history of having had some epigastric discomfort, described as a feeling of constriction of the abdominal muscles at the epigastric area, which came with eating or drinking and lasted about five minutes. He had had frequent chills and sweats during his illness and had been unable to sleep. On the evening of the date of admission his temperature was 105 F. No change of diagnosis or tentative diagnosis was made on his admission.

On November 6 a blood count showed 27,700 white cells, and a differential count showed 1 per cent small mononuclears, 4 per cent large mononuclears, 61 per cent neutrophils and 34 per cent eosinophils. This great increase in the percentage of eosinophils, together with other symptoms, particularly muscular soreness, served to establish a diagnosis of trichinosis.

On November 9, procaine hydrochloride and the procaine being used, a small piece of the gastrocnemius muscle

was removed, and numerous trichinella spiralis parasites were found by microscopic examination.

The surgeon at Camp Smith was informed by telephone that a diagnosis of trichinosis had been made in the case of enrollee A. At that time Dr. Schulze, the camp surgeon, stated that he had admitted within the past two days patients with the same symptoms, who probably also had trichinosis.

On November 8 Dr. Schulze evacuated to the Station Hospital seven patients, all of whom had a fever, swollen eyes and muscular soreness. Later, as other enrollees reported at sick call, those with trichinosis were selected for transfer by their fever, swollen eyes, muscular soreness and eosinophilia. Four patients were transferred on November 9, nine on November 10, eleven on November 11, five on November 13, one on November 15, four on November 16, one on November 18 and one on November 23.

An epidemiologic study was immediately started at Camp Smith. Many of the enrollees who were ill with trichinosis had returned from Oregon on October 13, and because of that fact it was not necessary to go beyond that date. Pork had been eaten as follows: October 13, sausage meat (breakfast), October 16, salt pork (supper), October 17, sausage meat (breakfast), October 19, bacon (breakfast), October 19, chops (supper), October 23, salt pork (supper), October 24, sausage links (breakfast), October 27, roast loin (dinner), October 30, salt pork (supper), and October 31, roast cured ham (dinner).

The sausage meat on October 13 and 17 was furnished by the Camp Charles M. Smith Experimental Farm. All the other meat was furnished by well known packing houses under contract. All of the meat had been inspected locally by a veterinary officer assigned

Fig. 1—Enrollee S showing marked ecchymosis of the corner and edema of the face and eyelids.

to that duty, and in addition meat products from the packing houses had been inspected by the Bureau of Animal Industry. Organization commanders and mess sergeants of the Civilian Conservation Corps are required to inspect carefully all meat products served, after cooking. They had done so in the case of the infested pork loin at dinner on October 27.

By questioning the enrollees and by examination of the company morning report and records, it was

determined that the only meal at which all enrollees had been present and in whom trichinosis subsequently developed was on October 27, when a roast loin of pork was served, which many of the enrollees said was undercooked in the center.

This date and the source of the epidemic were somewhat confused because of the case of enrollee A, who was admitted to the camp dispensary on October 30 and to the Station Hospital on November 5. On his admission to the camp dispensary on October 30 his chief complaint was symptoms of disease of the upper respiratory tract, moderately severe acute coryza and severe pharyngitis which required treatment.

On October 30, the day of admission, the medical officer attending him noted that he had some swelling of his upper eyelids, suborbital edema and inflammation of the conjunctiva. The respiratory symptoms continued to predominate, however, until November 3, by which time the coryza and pharyngitis had gradually improved but the elevation of temperature and particularly the pain around the eyes and the swelling of the eyelids remained. It can therefore be assumed that during the first part of his illness, which began on October 27, the patient was suffering from an acute infection of the respiratory tract and not from trichinosis, which supervened three days later. He had eaten the pork loin on October 27.

He had been detailed as a kitchen helper from October 1 and had assisted several times in preparing the pork and beans served. Each time he ate several cubes of the raw salt pork.

Enrollee A had clinically the most severe trichinosis in the epidemic. His biopsy showed an infestation of 800 larvae per gram of muscle. An incubation period of three days was assigned in his case.

It was important to determine the exact date on which the infested pork was eaten in order that a correct incubation period might be ascertained. The incubation period given in most textbooks is from one to forty days. No average is stated. It is fortunate that for this epidemic, caused by an infestation of intermediate extent, an average incubation period can be computed. For forty-four cases the average incubation period was twelve and four-tenths days, the minimum period was three days and the maximum period was twenty days.

Five quantitative biopsies were made, with the following results: enrollee A, weight 66.6 Kg, 800 larvae per gram, enrollee S, weight 61.4 Kg, 33 larvae per gram, enrollee I. T., weight 80.9 Kg, 8 larvae per gram, enrollee T, weight 65.4 Kg, 22 larvae per gram, and enrollee C. W., weight 64.5 Kg, 50 larvae per

Fig. 2—Enrollee C. W. showing the characteristic drowsy appearance associated with trichinosis, edema of the upper eyelids, suborbital edema and swelling of the face.

gram All biopsy specimens examined showed living larvae, with beginning encystment, December 10

The number of larvae contained in the muscles of enrollee A was estimated Assuming that half his body weight is muscle, he had a total of 26,640,000 living larvae in his muscles

Dr Maurice C Hall and Dr Benjamin J Collins,¹ both of the Division of Zoology, National Institute of Health, United States Public Health Service, stated that in autopsies performed at hospitals in Washington, D C, and Baltimore, on 300 persons who had died from causes other than trichinosis, forty-one diaphragms were seen to be infested with trichinellae We have been informed² that examination of 1,000 diaphragms from autopsies at hospitals with a greater geographic distribution has shown this percentage to be increased, and it may be assumed that a great many persons have had trichinosis, either with or without symptoms

With this information in mind and with the aid of a technical assistant, Dr John Bozicevich from the National Institute of Health, United States Public Health Service, we tested by the cutaneous and the precipitin method the forty-four patients with trichinosis in the Station Hospital and all CCC enrollees remaining on duty at the 1136th Company Both tests were positive for all of the forty-four patients in the Station Hospital At Camp Smith 136 enrollees still on duty in the 1136th Company were tested, twenty gave positive reactions to the cutaneous and the precipitin test Seven of these twenty gave a history of no symptoms whatever, five had been under observation or treatment at the camp dispensary for trichinosis with a negative result and were permitted to return to duty, the eight remaining enrollees had had indefinite symptoms of a cold, with swollen conjunctiva and painful eyeballs, or had experienced muscular weakness or malaise for two or more days At the time of examination, however, all were on duty and did not desire to go on sick report, since they felt entirely well

In this examination fifty control subjects in the 1184th Company at Fort Ethan Allen, Vt, were tested, furnishing a corresponding social group of the same age and living conditions as those of the 1136th Company at Waterbury Of these fifty, only two showed a mildly positive reaction to the cutaneous test and all gave a negative reaction to the precipitin test

It may be mentioned that Dr Bozicevich has spent considerable time in an attempt to refine the antigen used in the cutaneous test for trichinosis, and it now appears that his antigen is very satisfactory, a substantial contribution toward progress in the diagnosis of trichinosis

As shown by the cutaneous and the precipitin tests, twenty cases of so-called ambulatory trichinosis at Camp Smith may be added to the forty-four cases in the Station Hospital, making a total of sixty-four cases in the epidemic In other words, approximately one third of the patients in this epidemic were ambulatory

Owing to careful selection and careful attention to hospitalization, the incidence of hospital cases is probably higher in the Civilian Conservation Corps than it would be in an epidemic in the civilian population, in which it can be assumed that about 50 per cent would remain ambulatory or semiambulatory during their illness It

is reasonable to assume that in future epidemics involving an infestation of intermediate extent, this ratio would obtain

The forty-four patients now under treatment in the hospital have made satisfactory progress to date (Dec 20, 1937) Their symptoms and further progress will be reported in a later paper It has been possible to secure excellent clinical histories for the reason that on October 1, six students from the University of Vermont were assigned to the Station Hospital for fourth year clinical work The facilities of the University of Vermont have therefore been available for study of the cases, and the work is now being done At a later date it is proposed to publish papers on the symptomatology and on a study of the eosinophilia and the blood chemistry in trichinosis

From this report it is possible to draw certain conclusions regarding the prevention of trichinosis Official meat inspection does not eliminate the possibility of infection Education of the public to the danger of infection appears difficult Much cooking is done in the kitchen by hired help who know little or nothing about trichinosis An extensive campaign of education would serve to alarm people to the extent that they would refuse to eat pork at all This fact does not preclude, however, mention of the reason for thorough cooking of pork whenever and wherever advice is given on general public health methods or measures

The United States Public Health Service is of the opinion that garbage-fed hogs are responsible for the great prevalence of trichinae in pork at the present time, and Dr Maurice C Hall³ stated that

Garbage-fed swine have trichinae between three and five times as frequently as do grain-fed swine and hence are specially important as sources of human trichinosis

Trichinosis in swine is apparently traceable to the eating of uncooked pork scraps in garbage, table scraps, swill and similar things much more often than it is traceable to the eating of rats by swine

The garbage feeding industry, as ordinarily carried on is dangerous to the health of man and livestock, esthetically objectionable, and often economically unsound

It appears therefore that a broad approach must be made to the problem of prevention of trichinosis to include inspection of pork products by official source education of the public to the dangers of eating raw or uncooked pork and elimination of the garbage feeding industry as now carried on

SUMMARY

In this epidemic there were forty-four patients with trichinosis who required hospital treatment and twenty ambulatory patients with little or no sick record

An average incubation period of twelve and four tenths days was definitely established for the epidemic

Five quantitative biopsies showed from 8 to 260 living larvae per gram of muscle

A preliminary survey of work now being done on autopsy material by the National Institute of Health United States Public Health Service, indicates that many individuals have become infested with trichina larvae

The improved antigen demonstrated a dependable accuracy in the cutaneous tests of 180 persons concerned in the epidemic and fifty control subjects

Preventive measures against trichinosis should include prevention of the disease in swine as well as in man

Clinical Notes, Suggestions and New Instruments

MINUTE PERFORATION OF AN ARTERIOSCLEROTIC PLAQUE WITH RESULTANT RETROPERITONEAL HEMATOMA

V EUGENE FRAZIER MD KANSAS CITY MO

Recently while I was working on the staff of the Army and Navy General Hospital, a most perplexing case was admitted to the medical service, under my observation. Because of the inability of any of the staff to make a satisfactory diagnosis and because of the unusual condition found at postmortem examination I feel that this case is worthy of being reported. In my investigation of the literature that was available to me nowhere was I able to find the report of a like condition.

REPORT OF CASE

History—W C, a white man, aged 63, a resident of a small Arkansas town, was admitted to the hospital March 30, 1936. The diagnosis that was transmitted with the patient at the time of admission was (1) unresolved pneumonia of the left lower lobe, (2) acute constipation and (3) chronic arthritis. These diagnoses had presumably been made by the patient's family physician. The patient was a carpenter however since 1926 he had worked at only odd jobs. He had been in Florida from 1925 to 1929, otherwise he had spent all his life in a temperate climate. He was an occasional drinker and a constant pipe smoker. The past history included mumps during childhood, gonorrhea in 1902, progressive deafness for ten years and frequent attacks of malaria all during his life. The family history was irrelevant.

On admission the patient complained chiefly of pain in the back, anorexia and constipation. The soreness in the back was traced about ten years. The region involved was from the midsorsal to the coccyx. The severity was such that a physician was frequently summoned and a 'hypo' given for relief. Because of this circumstance the patient had forsaken his trade and resorted to such light tasks as he was able to find. The attacks would last for a month or more and were separated by an interval of several months. He stated that during this ten year period whenever he leaned over or attempted to lift anything he would always have a pain in the back and would feel too weak to complete the execution of the movement. The attacks had been of progressive severity the one that occasioned this hospitalization having been the most severe of any to date, having appeared Feb 15, 1936 and continued without remission until admission. During the present illness he had been constantly under the care of his family physician. There had been anorexia, vomiting was slight and constipation had been moderate. No other symptoms referable to the gastrointestinal tract were mentioned.

Physical Examination—The patient was admitted on a litter conscious and rational. The nutritional state and general health appeared fair obviously, however he was seriously ill and in great discomfort. He answered questions very slowly but rationally. He was reluctant to make any unnecessary movements or to indulge in any conversation. The estimated weight was 145 pounds (66 Kg) the height 67 inches (170 cm). The pupils reacted to light and to accommodation. Hearing was defective the teeth had all been removed the tonsils were small and not noticeably infected. The skin and mucous membranes appeared normal for one of his age and habitus. There was no adenopathy the thyroid was not palpable. Sclerosis of the temporal and radial arteries appeared normal for his age or possibly somewhat increased. The blood pressure was 130 systolic 90 diastolic. The cardiac rate and rhythm were considered normal the apex impulse was not palpable the heart was not enlarged to percussion and no murmurs were audible. The lungs were considered normal to inspection palpation percussion and auscultation. The abdomen was flat and there was slight rigidity. There was moderate tenderness over the entire upper half of the abdomen. In the center of the upper half of the abdomen there was a readily palpable mass which seemed hard and immobile this

measured about 20 cm in diameter. The pulsations of the aorta were palpable with ease over the mass. Examination of the genito-urinary tract was considered negative. The prostate was considered to be of normal size and consistency. The reflexes were all normal, as were also the bones, joints and muscles.

Progress—The patient was placed on a liquid diet and was given opiates in sufficient quantity to control the pain. After four days the condition had become worse, and intravenous infusion of saline and dextrose solution was given. At this time consultation was held with the surgical service and immediate exploratory laparotomy was decided on, the consensus being that an abdominal aortic aneurysm would be found. A midline incision was made, and immediately on palpating a retroperitoneal tumor the surgeon announced the finding of an aneurysm. After palpation, each of the assistants concurred. Because of the condition of the patient the abdomen was closed without any further investigation being attempted. During the operation a transfusion of 500 cc of citrated whole blood was given, and also lobeline and coramin were given. The postoperative course was uneventful but very slow, until the eleventh day, when the patient fell out of bed, thus tearing the upper half of the incision open. The condition continued to be poor, and gradually the patient became weaker. At times he was irrational and vomited occasionally, sometimes blood was seen in the vomitus. Fluids were taken freely, but no other food was given.

On the ninth postoperative day the dressings were blood stained and needed frequent changing, no improvement in this regard occurred. The temperature did not exceed 101 F at any time during the hospitalization. April 21, on the eighteenth postoperative day, the patient died.

Laboratory Study—The urine showed a trace of albumin and a few hyaline casts but otherwise it was normal. Examination of the feces was negative for blood and parasites. The blood count, March 30 showed red blood cells 4,820,000, hemoglobin 95 per cent, white blood cells 12,800. Lymphocytes 23 per cent, monocytes 1 per cent and neutrophils 76 per cent. April 13 red blood cells 4,220,000 hemoglobin 85 per cent white blood cells 11,900, lymphocytes 27 per cent monocytes 1 per cent and neutrophils 71 per cent, April 17 white blood cells 10,600 lymphocytes 14 per cent monocytes 2 per cent and neutrophils 84 per cent. The bleeding time was four minutes, the coagulation time four and one-half minutes. The Wassermann and Kahn reactions were negative on two occasions. Analysis of the gastric contents revealed total acidity 30/24/51 free acidity 0/10/20, occult blood positive/negative/negative/negative/positive.

X-Ray Study—Owing to the weakened condition of the patient the x-ray examination was reduced to the minimum. In the hilus of the left lung there was an oval shadow of increased density which suggested the differentiation between tumor aneurysm, paraspinal abscess and diverticulum. There was a gross defect of the pyloric portion of the stomach and in this region peristalsis could not be demonstrated. The six hour examination showed partial retention and the filling defect was again seen. The duodenum filled spontaneously and appeared normal. Films made to show the thoracic and lumbar spine were negative. The colon was not visualized. No other lesions were demonstrated.

Autopsy—The coronary arteries appeared normal. The aortic arch and the upper part of the descending aorta appeared normal with the exception of small scattered atheromatous plaques. Just above the diaphragm these became more numerous and of larger size and as the celiac axis was reached the plaques became coalescent. Just below this point there was a minute rupture on the right side of the vessel which was accompanied by a large hemorrhagic infiltration that was apparently slowly formed and seemed to have followed along the right renal artery into the perirenal fat. This had produced a large retroperitoneal hematoma which had roughly the shape of a kidney and which measured 16 by 9 by 7 cm. The mass was tense and seemed to involve the fat and connective tissue. The kidney was enclosed within the hematoma but no blood was found in the renal pelvis. Within the mass were old clots which were in layers but not organized. The renal

capsule was intact and had not been penetrated by the hemorrhage. The renal artery was intact and appeared normal. Below the perforation the aorta appeared intact, but many of the sclerotic plaques were ulcerated. There was no free fluid in the abdominal cavity. The autopsy revealed no other significant lesions. Histologically the changes were typical of arteriosclerosis.

SUBCUTANEOUS RUPTURE OF THE JEJUNUM SUSTAINED IN A GAME OF FOOTBALL

W. H. ULRICH, M.D., J. E. WEBSTER, M.D., AND
C. FREMONT VALE, M.D., DETROIT

Catastrophic injuries incurred while playing football are not common. Christopher¹ in 1934 stated that rupture of the intestine due to sport injuries is apparently exceedingly rare. He reported one case at this time and noted the reports of three others by Nadler² and Kinzel.³ In view of widespread football interest, it appears timely to point out the possibility of this type of accident and to report a case which came under our care.

The following is the report of a high school football player having a subcutaneous rupture of the jejunum, operated on twenty-five hours after sustaining the injury and making a recovery.

History—G. C., a white youth, aged 19, was apparently kicked in the abdomen while engaged in tackling an opposing player. The kick was alleged to have taken place as the patient's abdomen met the moving foot of the opponent. Almost at the same time the patient fell forward, the abdomen hitting the ground rather violently, suggesting a second possibility for origin of the trauma. The injury occurred at 4 p. m. Oct. 13, 1936. The patient was breathless, his "wind having been knocked out." Going to the showers, after he regained his wind, he experienced cramplike abdominal pain. He vomited partially digested apples eaten just before practice. He was told to take a warm shower, which he did, obtaining complete relief from the abdominal pain. When he reached home he experienced similar cramping pains somewhat more severe and more continuous. Given peppermint drops, he immediately vomited, repetition produced the same result. The patient entered Receiving Hospital at 9 o'clock, five hours after the injury.

Examination—The patient appeared healthy and was well developed and nourished. He was 5 feet 8 inches (173 cm.) tall and weighed 160 pounds (72.6 Kg.). He had a normal temperature and pulse on admission. He did not appear ill and had only moderate concern for his abdominal pain, insisting that it was improving. Careful examination of the head, chest, heart, back and extremities revealed no evidence of injury or intrinsic pathologic changes. The systolic blood pressure was 120, the diastolic 76. The abdomen, which was symmetrical in contour, presented marked tenderness limited to the hypogastrium and was associated with muscle spasm mainly of voluntary character. Rebound tenderness was not present. No distention or fluid could be elicited. The patient voided voluntarily. Laboratory studies revealed urine normal, hemoglobin 13 Gm., color index 0.8, red blood cells 4,700,000, white blood cells 22,200 with 28 per cent nonfilaments, 66 per cent filaments and 6 per cent lymphocytes.

The impression at this time was that the patient had sustained an intra-abdominal accident and that prompt operation was imperative. This suggestion was met by stubborn refusal on the part of the patient and his father.

Preoperative Interval—The patient slept fairly well during the night, awakening occasionally and complaining of moderate pain. At 6 a. m. October 14, he said that he was somewhat nauseated but wanted something to eat. Further attempts made to convince both the father and the patient that exploration was necessary were futile. The father was finally persuaded to call the family physician, who in turn emphasized the urgent need for operation. At 4 p. m., the patient vomited for the first time since hospitalization, pain increased, and with this unfavorable trend consent for operation was obtained. Examination of the

abdomen at this time showed the tenderness to be in the epigastrium and the left upper quadrant. Rebound tenderness was present. Moderate involuntary rigidity was present in the upper portion of the abdomen. There was no distention. In the interval the patient's temperature had risen to 100.8 F. at 8 a. m., falling to 99 F. at 4 p. m. The pulse at 8 a. m. was 54 and at noon 130, falling to 90 just before operation.

Operation—This was begun at 5 p. m. under gas ether anesthesia, twenty-five hours after the accident. By means of a left rectus incision, the abdominal cavity was opened. A large quantity of turbid fluid escaped and by suction approximately 1,000 cc. of fluid was removed. Partially digested beans were present in the fluid. Large plaques of fibrinous exudate covered coils of small intestine in the upper left quadrant. Examination revealed that the stomach was intact. There was a longitudinal tear fully 2½ inches (6.4 cm.) long in the antimesenteric surface of the jejunum about 1 inch (2.5 cm.) below the ligament of Treitz. Closure was effected, reinforced by a Lembert suture. Further exploration revealed no other evidence of injury except a contusion to the transverse colon with subserosal hemorrhage. Drainage of the pelvis and lateral gutters were established by appropriate incisions and drains.

Postoperative Course—The patient's immediate postoperative state was critical. The pulse rate rose to 160 and the temperature to 106 F. within the first twenty-four hours. Gradual improvement then occurred, marked by a steadily declining temperature and pulse rate, which reached normal on the eighth postoperative day. Normal for three days, the temperature then became irregular, reaching a maximum of 101 F., the result of an infection of the incision. On the twenty-first postoperative day signs and symptoms of a partial intestinal obstruction appeared. Conservative therapy by suction drainage of the stomach proved effective. Healing of the wound occurred by second intention, resulting in a prolonged hospital stay of forty-seven days and an incisional hernia. A gastro-intestinal series prior to discharge revealed no abnormalities.

The patient returned four months after discharge for the repair of the incisional hernia and made an uneventful recovery. He is now in excellent health.

COMBINED EXTRA-UTERINE AND INTRA-UTERINE PREGNANCY

E. JOHN DOLAN, M.D., NEW YORK

This is the report of a case of combined extra-uterine and intra-uterine pregnancy which resulted in a living issue. Because this condition is comparatively rare and because it results in a full term child in only a small proportion, I feel justified in making this presentation.

Ectopic gestation occurs, according to Schumann,¹ one in 303 pregnancies. Parry,² in an early review, found in 500 ectopic gestations twenty-two that were complicated by a simultaneous intra-uterine conception. To date there have been approximately 300 of this type reported. How many of these progressed to a full term uterine delivery is hard to say, but in the thirty-four cases reported by Novak,³ twelve, or 35.3 per cent, were known to have resulted in a living child.

REPORT OF CASE

A white woman, aged 28, was brought into the Westchester Square Hospital by ambulance. There was nothing significant in the past history. A few hours before entrance she had a sudden severe pain in the left lower quadrant. There was no nausea or vomiting nor were there any urinary complaints. She had had irregular menses during the past few months and amenorrhea for the past six weeks, with some spotting two weeks before entrance.

The patient appeared acutely ill and pale but not in shock. She was alert and cooperative and the pulse was rapid but of good quality. Physical examination was essentially negative.

except for rigidity and severe tenderness, with rebound tenderness in the left lower quadrant. Pelvic examination revealed a very tender cervix especially on motion. The cervix was soft. A tender palpable mass was felt on the left side. A diagnosis of ruptured ectopic pregnancy was made and operation was performed within a few hours.

When the abdomen was opened free blood was found in the peritoneal cavity. The left tube was ruptured and contained a two to three months fetus. The tube and the ovary were removed. The uterus showed enlargement and had the appearance of being pregnant. The abdomen was closed with a Penrose drain. The patient made an uneventful recovery and was discharged from the hospital twelve days after the operation.

The amenorrhea continued until the patient was again admitted to the hospital October 11 (six months and twenty days after operation), at which time she was delivered spontaneously of a full term normal child. The weight of the baby at birth was 8 pounds 3 ounces (3,714 Gm). The postpartum course was normal and the patient was discharged ten days later. The child was normal in every way.

COMMENT

It is of interest to note that Parry was able to collect twenty-two cases of this condition reported before 1876. Later authors are of the opinion that the present rate of occurrence will increase with more widely applied scientific observation.

As Novak pointed out, most of these cases can be considered twin pregnancies. There are some on record, however, that are undoubtedly gestations superimposed on earlier ones. The case here reported appears to be of the twin pregnancy type.

The condition occurs largely in young women and in those with personal or family histories of multiple gestations.

The diagnosis is difficult, particularly in the earlier stages, as some cases are predominantly ectopic while others are predominantly uterine. In this case the menstrual history was very suggestive of the ectopic pregnancy. Even the enlarged uterus with softened cervix that was found might be an accompaniment of the tubal gestation.

2325 University Avenue

HEAT SENSITIVENESS ASSOCIATED WITH DERMATITIS AND POLLEN ATOPY

EDWARD W. MISKALL, M.D., FAST LIVERPOOL, OHIO

History—B. C., a white youth, aged 17, a student, consulted me March 25, 1936, complaining of a cutaneous eruption of the hands and fingers and attacks of generalized urticaria. The cutaneous lesions were first noticed simultaneously with symptoms of hay fever in June 1935, immediately after the patient had been pulling weeds. He attributed the symptoms to paint, which he had used that day, but avoidance of further contact with the paint had no effect on the symptoms and various local treatments applied since had been equally ineffective. The hay fever subsided in the late summer but the cutaneous lesions persisted. In January 1936 a severe attack of scarlet fever was followed by episodes of generalized urticaria, apparently consequent on exertion or on coming into a warm room. These attacks began with subjective sensation of heat and generalized flushing of the skin followed in a few minutes by generalized wheals. Cold air brought immediate relief.

The parents stated that the patient was a 'blue baby,' had never been strong and had frequently complained of pains around the heart, also that he had had convulsions in childhood following applications of camphor and menthol ointments and after quinine by mouth. He had had measles, pertussis and chickenpox in childhood, diphtheria at 6 followed by cervical adenitis of six weeks duration, and a tonsillectomy at 11.

No allergy, heart disease or tuberculosis was known to have occurred in the family.

Examination—The patient was pale and asthenic without cyanosis, edema or icterus. The temperature at 1 p.m. was 98.6 F., the blood pressure 122 systolic, 76 diastolic, his weight 125 pounds (56.7 kg.) and his height 69½ inches (177 cm.). The nasal septum was deviated to the right with partial obstruction. The heart and lungs were entirely normal.

Nothing abnormal was noted on examination of the abdomen, genitalia, rectum, reflexes and lymph glands. An impetiginous dermatitis covered the hands and fingers. There was moderate dermatographism.

The urinalysis and the blood count were entirely normal. There was no eosinophilia. The Wassermann and Kahn reactions were negative. The basal metabolic rate was 0 and plus 5 per cent on consecutive days.

Patch tests with camphor and menthol (1 per cent in oil), body paint and Japanese dryer (10 per cent in oil), allergenic oils of orchard grass, sweet vernal grass and timothy were negative. A test with crushed leaf of timothy, as suggested by Dr. Coca¹ could not be carried out. Scratch tests with quinine hydrochloride 1 per cent in water and with quinine sulfate 1:40 in glycerin² were negative, with timothy, orchard, sweet vernal and June grasses, 4 plus. Temperature tests: A square of gauze wrung out of hot water and applied to the forearm produced in five minutes localized marked erythema and urticaria. Immersing the forearm in water at 100 F. produced in seven minutes localized urticaria, which disappeared quickly in cold water. Room temperature of 80 F. produced generalized urticaria, as did vigorous exercise. Ice applied to the skin was without effect. Orally, quinine sulfate and quinidine, 0.3 Gm. each, were without ill effect. The patient declined further allergic studies.

Treatments—Intensive preseasonal desensitization to offending pollens was followed by a mild attack of hay fever in 1936. Local treatments were applied to the hands as follows: boric acid soaks, an ointment of tar, mercury and Burrow's solution, treatments of one-fourth unit of unfiltered γ -rays, 2 milliamperes, 6 inch spark gap, 8 inch distance, forty-five seconds. Heat sensitiveness was treated by graduated exercises and by baths beginning with thirty seconds at 65 F. and increasing daily in time and temperature until thirty minutes at 90 F. produced no urticaria. By midsummer urticarial attacks were rare and very mild, but the dermatosis was only slightly improved. The patient was not observed in 1937.

COMMENT

It may be doubted that the dermatitis in this case was due to pollen, since it did not show seasonal variation and patch tests were negative. There was no opportunity for further patch testing with the crushed leaves of the suspected plants. Brown, Milford and Coca³ place pollen dermatitis in the class of contact dermatitides, with a basis in sensitivity comparable to ivy, sumac or primrose sensitiveness. They feel that it is not confined to persons subject to atopic hereditary influence but occurs in nonatopic persons as well. Grass dermatitis (spring group) is much rarer than ragweed dermatitis. Various dermatoses are recorded as being associated with physical allergy⁴ but in the case here reported the dermatosis preceded the urticaria by six months, the latter following immediately on scarlet fever. Several of Duke's⁵ cases of heat sensitiveness followed acute febrile illnesses. Whether a relationship exists in this case between the dermatosis and the heat sensitiveness is doubtful. C. H. Rowe⁶ holds that heat sensitiveness is an unusual manifestation of food allergy. George Piness⁷ is not in accord and maintains a nonallergic explanation of heat sensitiveness. Urbach and Finkel⁸ reject the term physical allergy for the great majority of cases and suggest the term vasoneuropathy of physical origin. They think it not improbable that successful desensitization will be found to be of the nature of a nonspecific hypodermic rather than a phenomenon of specific allergic immunity.

STRYCHNINE POISONING SUCCESSFULLY TREATED
WITH SODIUM AMYTAL

REPORT OF TWO CASES

ROBERT E. PRIEST, MD WORTHINGTON MINN

Strychnine poisoning is a common cause of suicidal and accidental death. It appeals to one contemplating suicide because of its cheapness, accessibility and small lethal dosage. Sugar coated strychnine tablets intended for adult medication tempt children. About one third of the accidental deaths from 1926 to 1928 in children under 5 years of age insured by the Metropolitan Life Insurance Company were caused by strychnine.¹

Many antidotes for strychnine poisoning have been suggested. One group of authors list twenty-six.² These include inhalation anesthetics, stimulants, vasodilators, sedatives and even bleeding. Emetics have also been used.³ Not one of these methods is specific, many are ineffective and few can be accurately controlled.

In 1929 Zervas and McCallum⁴ reported three cases of strychnine poisoning in human beings successfully treated with barbiturates. Lundy⁵ commented on the successful use of barbiturates in strychnine poisoning in 1931. I have found more recent reports of eleven cases in which treatment with sodium amytal was successful, and three cases in which other barbiturates were successfully used.⁶ There probably are others.

Because so few reports were found I thought that an account of two more patients successfully treated with sodium amytal might be of interest.

The physiology of the protective action of barbiturates against strychnine poisoning has been studied in animals by several investigators.⁷ Various barbiturates have been shown to act as antidotes against strychnine in unanesthetized rats and rabbits. Swanson⁸ showed that "sodium amytal by vein in small repeated doses antidotes 20, 25, 30 and up to 35 times the subcutaneous minimum lethal dose of strychnine sulfate in rabbits."

REPORT OF CASES

CASE 1—W. M., a white man, aged 60, a farmer, became despondent over family affairs. At about 7:30 p. m., May 7, 1935, he mixed approximately 15 Gm (230 grains) of strychnine sulfate with water and drank it. He had just eaten his supper. He became extremely nauseated and vomited the meal and probably part of the strychnine. At 9 o'clock when I examined the patient he was in opisthotonos with all skeletal muscles contracted. When the muscles relaxed momentarily he told me that I could do him no good—that all was over. He was given 0.5 Gm (7½ grains) of sodium amytal intravenously. The muscles relaxed a few moments later and by 9:15 he was sound asleep.

My attention was then called to the patient's dog, which had been seen eating the vomitus in the yard and was now

lying rigid. I gave him 0.5 Gm (7½ grains) of sodium amytal intraperitoneally and the muscles relaxed almost immediately and he ran off.

The patient was brought to the hospital. About midnight the muscles became spastic again. The dose of sodium amytal was repeated. The patient slept all night and had no more spasms. In the morning he said that his body felt as if it had been beaten.

The dog did not fare as well as his master and was found dead the next morning. His posture suggested that he died in a strychnine convulsion.

CASE 2—G. H., a white man, aged 56, a farmer, was brought to probate court May 15, 1937, for examination prior to commitment to a state hospital for inebriates. About fifteen minutes had elapsed from the time the sheriff took him from his farm until he reached court. As he entered the courtroom his legs became spastic. He said that he had taken poison when he saw the sheriff approach his farm. He refused to say what poison he had taken.

Because of the spasticity the poison was thought to be strychnine and the man was removed to the hospital quickly, where 0.5 Gm (7½ grains) of sodium amytal was injected intravenously. He slept ten minutes, then awakened. Tetani returned in a few moments. Complete rigidity of the legs could be elicited by a very slight jar of the bed. The dose of sodium amytal was repeated and the stomach was lavaged. The patient awakened in one hour with hyperactive reflexes. These gradually diminished and the patient slept. Fourteen hours later he awakened. His reflexes were still hyperactive but no other evidence of poisoning was present.

A specimen of the coffee with which the poison had been mixed was examined and was found to contain strychnine.⁹

Worthington Clinic

EAR PHENOMENON IN LESIONS OF THE
SYMPATHETIC NERVE

GEORGE B. HASSIN, MD CHICAGO

Professor of Neurology, University of Illinois College of Medicine
Attending Neurologist, Cook County Hospital

Lesions of the sympathetic nerve in the cervical region or in the medulla oblongata cause among other pathologic features a typical triad known as the Horner or Horner-Bernard syndrome: narrowing of the palpebral aperture, miosis and enophthalmos, all on the side of the lesion. The narrowing of the palpebral aperture is due to paralysis of the tarsal muscle, which participates in the closure of the eye. Miosis is due to paralysis of the dilator of the pupil, and the enophthalmos to paralysis of the orbital muscle of Muller. In addition, one may observe protrusion of the pinna of the ear on the side of the lesion.

When one compares the two ears in a patient who has a lesion of the cervical sympathetic, it is easy to notice that on the healthy side the distance between the pinna of the ear and the mastoid is smaller than on the affected side and that the ear is somewhat drawn backward. It can be noticed by the examiner either by facing the ears or by comparing them from behind. This phenomenon has been observed by me for many years in lesions of the lateral or retro-olivary region of the medulla which is nourished by the posterior inferior cerebellar artery.

This area contains pathways conducting the sensations of pain and temperature for the ipsilateral side of the face (descending root fibers of the trigeminal nerve) and the contralateral side of the body (the lateral spinothalamic tract). The crossed dissociated sensory disturbances and the Horner syndrome form the main features of what is known as Waller-Berg's syndrome of occlusion of the posterior inferior cerebellar artery. However, other lesions of the retro-olivary area—inflammatory or traumatic—of the medulla may also produce some features of this syndrome which is unquestionably due to involvement of the sympathetic nerve fibers, whether outside or within the medulla. This has been demonstrated by Laroche.

and Sherrington¹ in monkeys. By electrical stimulation of the upper end of the divided cervical sympathetic nerve they produced, among other phenomena, a slight drawing backward of the pinna of the ear, so that it lay closer to the mastoid region and projected less from the side of the head. On the other hand, mere sectioning of the sympathetic nerve of monkeys caused constriction of the pupil, narrowing of the palpebral aperture, chiefly by drooping of the upper eyelid but partly by raising the lower, and projection of the pinna from the side of the head. The clinical observations fully bear out the correctness of the physiologic observations, and it would be proper to call the ear phenomenon here described "Langley-Sherrington sign."

Special Article

OTHER FACTORS

LESS WELL KNOWN VITAMINS

C. M. McCAY, PH.D.

ITHACA, N. Y.

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. Reprints are not available but the articles will be published later in book form.—Ed

Under the title of "Other Factors" one can include only a few of the many essential organic substances that various animal species seem unable to synthesize. The description of these substances is scattered throughout the vast literature of biology. Many more have probably been missed than have been found. Such substances may seem of little importance at this time but who can say when the needs of some insect with specific requirements may provide the key for studying the vitamin physiology of higher species? These ramifications of nutrition are well illustrated by the discovery of Trager and co-workers that a factor essential for growth of mosquito larvae is present in normal human urine but deficient in that of pernicious anemia patients.

To appreciate the expanse of unexplored fields in the domain of nutrition one need merely read some modern work such as "Culture Methods for Invertebrate Animals" by Needham¹. All recent tests with insects indicate that they require special factors that have not been described thus far as essential for higher forms. Today one can only postulate that, as higher forms such as man lost their fins and acquired hands in the course of evolution, they also abandoned some of their primitive vitamin needs and acquired still others.

A detailed discussion of insect nutrition is not appropriate in this paper, but passing consideration is worth while. Some of the most primitive of insects, such as the common cockroach, require constituents of yeast such as the vitamin B fractions as well as other factors which still remain undescribed². Crowell and McCay³ found that even clothes moths require some of the fractions of yeast. No clear-cut evidence has ever appeared,

on the other hand, which indicates that any insect species requires either vitamin A or D, although certain lipid materials, possibly sterols, seem essential to such forms as the cockroach. As the insect field is explored further it is likely that needs for the fat soluble vitamins may appear.

Trager⁴ in discussing the nutrition of mosquito larvae concluded that there must be certain compounds other than the recognized vitamins that are essential. Frost and others found that mosquito larvae need certain essentials in yeast but not vitamin A, B, C, D or E. Fortunately, students of insect nutrition have recognized the limitations in the alphabet and have not attempted to label their discoveries with letters and subscripts. Such consideration for the future of the science of nutrition, however, must not be rewarded by neglect of their discoveries.

If one considers still lower forms than insects, one must enter the field of bacterial nutrition, where other parts of the alphabet, such as V and X, have been used to describe specific factors. Knight⁵ has provided an excellent summary of the nutrition of bacteria with considerable space devoted to vitamin factors. The possible usefulness of even the molds in assaying the vitamins is forecast in the recent study of Meiklejohn⁶.

The minute amount of growth stimulants with which the nutrition student of the future will have to be concerned is suggested in the recent studies of Kogl,⁷ who has isolated a factor for yeast which acts in a concentration of one part in four hundred billion. The comparative activity of some new and old compounds are shown in the accompanying table, from Kogl⁸.

Little attention has been devoted to invertebrates other than the insects. However, Wulzen⁹ and her associates have devoted many years to the study of planaria. In her earliest studies Wulzen recognized that

Comparative Activity of Several Compounds

| Material | Organism | Dilution | Effect |
|-------------|------------|-------------------|---------------|
| Biotin | Yeast | 1 400 000 000 000 | Growth |
| Biotin | Yeast | 1 40 000 000 000 | Growth |
| Auxin A | Carrot | 1 10 000 000 000 | Retardation |
| Auxin A | Oats | 1 1 000 000 000 | Curvature |
| Thyroxine | Tadpole | 1 5 000 000 000 | Metamorphosis |
| Epinephrine | Frog's eye | 1 20 000 000 | Expansion |

she was dealing with specific thermolabile substances that differ from the vitamins previously described. In recent attempts to isolate these factors, Greenberg and Schmidt⁹ have concluded that they can be extracted from liver by ether but that they are not identical with either the phosphatids or the nonsaponifiable lipids. Bahrs¹⁰ has found marked differences in the growth promoting power of the rabbit's intestine when fed to planaria, depending on such factors as age and diet of the rabbit. This opens a fertile field of investigation, planaria being used to assay tissues of higher forms.

FACTOR H

The lower vertebrates, with the exception of fish, have been given little attention by students of nutrition. For the past period of nearly a century during which trout have been domesticated it has been known that the various species require some factor present in fresh meat. After a series of studies in which trout were fed synthetic diets of purified constituents supplemented with yeast, tomato juice and cod liver oil, McCay, Bing and Dilley¹¹ found that trout could not live unless fed a small amount of fresh meat. This component was termed "factor H." In a series of later studies it was found to be thermolabile and readily destroyed in the course of ordinary drying. However, part of it was preserved when such sources as liver were dried in vacuo in inert gas. This substance is present in all fresh body tissues that have been studied. It seems to be the dominant factor in the nutrition of trout. The literature concerning this factor has been reviewed recently.¹² This factor seems to be essential for carnivorous species such as the fox and the mink. In many respects factor H resembles the thermolabile substance that Wulzen has found essential for planaria.

The letter H has also been applied to a totally different substance, which Boohar¹³ finds essential for rats. This factor is said to be heat stable but destroyed by alkali. She finds it essential for growth of the rat. Its relation to the similar factors postulated by others has been discussed in earlier chapters.

The term "vitamin H" has also been used at times by Paul Gyorgy¹⁴ to describe one of the fractions concerned in rat dermatitis. A recent German work has included an entire section under the heading of "vitamin H."¹⁵ In this summary Stepp and his co-authors define H as the dialyzable, heat stable substance which is set free from liver proteins by digestions and proteolytic enzymes, according to the observations of Gyorgy. They assume that this essential is needed by the rat, the chicken and man. There seems little justification for including all these diverse discoveries under this common name. Furthermore, one wonders why the term H should be used to describe the growth factor of Williams, Lewis or Hunt. Apparently the Germans are already marketing some preparations supposed to be concentrates of this factor under the names "Huco Salve" and "Murmil."

MISCELLANEOUS GROWTH FACTORS

The literature dealing with lower forms of life teems with unnamed and ill defined vitamins. There are fewer such factors described for the vertebrates that are popular with orthodox students of nutrition, namely, the rat and the chicken. Since most of these have been considered in other papers in this series, only brief mention of them need be made here.

The growth factor for chicks described by Arnold and his associates¹⁶ has proved to be the amino acid arginine, thus accounting for the growth stimulation by such products as peanut meal, liver residue and soy bean meal.

In 1931 Guha¹⁷ found that there were certain factors in milk, grass, spinach and egg yolk that stimulated the growth of rats fed B fractions in the form of vitamin B₁ and autoclaved marmite. To preserve the fractions he found it essential to dry the products at 35 C in front of a fan. The potency of these materials was lost in both fractions through extraction with ether.

Hogan and his co-workers¹⁸ have shown the need of herbivorous species for some factor that is present in plant juice or alfalfa. During the past two years, evidence has also accumulated in the Animal Nutrition Laboratory at Cornell that lambs require some factor other than the recognized vitamins, that is present in freshly sprouted oats. Kohler and his co-workers¹⁹ noted the growth stimulating properties of grass juice.

In 1929 Coward and her associates²⁰ found that some factor was contained in certain preparations of casein and was deficient in others. When a particular sample of casein proved deficient it could be supplemented satisfactorily by milk, lettuce, liver or wheat embryo. These studies were made with rats in the course of other assays.

Liver has provided a fertile source of growth stimulating factors. It has long been recognized that the essential constituent for brook trout, factor H, is richest in beef liver. Likewise the vitamin requirements of such lower forms as planaria are completely satisfied by liver. The past ten years has indicated that liver has several essential factors, and there is little doubt that many will be discovered as new species are considered by students of nutrition.

In 1932 Mapson²¹ postulated the existence of a growth factor in liver. It was soluble in 90 per cent alcohol and also in water after the liver was subjected to digestion with papain. This factor was named "physin." Seegers and his co-workers²² also found that liver contained a growth factor. This tended to be lost on heating. Liver heated at 100 C for two weeks lost this capacity to stimulate the growth of rats, although the biologic value remained unchanged as far as the protein was concerned.

Elvehjem and his associates²³ have postulated several new factors. Among them is included one for stimulating the growth of rats. They found this in the alcohol ether precipitate from water extract of hog's liver. They find this is heat labile, so it falls among the thermolabile B factors and needs no further discussion here, other than to note it with the other factors of liver. This factor has recently been christened W by Frost and Elvehjem²⁴.

Halliday and Evans²⁵ attempted to confirm the observations of Elvehjem and his co-workers but came to the conclusion that the precipitate from hog's liver

was carrying down vitamin B₆. Therefore they decided that there was inadequate evidence to postulate such a new factor.

The "Y factor" described by Chick and Copping²⁶ also is found in liver as well as in yeast and its water extracts. This factor is one of the B fractions needed for growth by the rat. Its nature is gradually becoming clear in the course of such thorough studies as those of Edgar and Macrae.²⁷ These authors find another factor adsorbed on fullers' earth which is neither vitamin B₆ nor riboflavin.

Among the liver extracts must also be included the filtrate factor of Lepkovsky and Jukes,²⁸ which seems potent in curing dermatitis in chicks, blacktongue in dogs and pellagra in man. This may be identical with the "Y factor," already described, and nicotinic acid, to be discussed later.

In order to rear chickens on synthetic diets, Hogan and his co-workers²⁹ had to supplement the basal diet with wheat germ oil, acid hydrolyzed yeast, tikitiki and liver extract in addition to carotene and irradiated ergosterol. One can only speculate concerning the undiscovered factors in such an array of supplements.

In 1928 Hunt³⁰ discovered that there were at least three factors in yeast that were essential for the growth of the rat.

In the course of growth studies with rats, Williams and Lewis³¹ also found a factor left in yeast residues after extraction with water and alcohol. This growth factor could not be extracted with any solvent. No later work indicates its relation to the new B fractions.

Vitamin I, or B₇, is the factor postulated by Centanni.³² He found that an alcoholic extract of rice polishings prevented digestive disturbances in pigeons but did not prevent the symptoms of polyneuritis. Methyl alcohol was the best solvent among the alcohols. Ethyl alcohol was effective at from 95 to 100 per cent but extracted only part of this factor at a 70 per cent concentration.

This I factor recalls the claims of Rosedale³³ made ten years ago. At that time he precipitated the water extract of rice polishings with lead acetate and carried down a factor that permitted evacuation of the bowels and checked the constipation associated with polyneuritis in birds.

This also recalls the factor of Carter.³⁴ He found that the heart rate slowed down when pigeons were fed polished rice but that recovery was much slower from feeding B₇ than from such feedstuffs as yeast and wheat. All these factors are difficult to evaluate, since polished rice is such an unbalanced diet in many respects.

Factor J is the term applied by von Euler and Malmberg³⁵ to a substance found in fruit, especially St John's berries. This factor seems to cure pneumonia in guinea pigs, while cevitamic acid will not.

VITAMIN K AND OTHER BLOOD CLOTTING FACTORS

Vitamin K is a specific fat soluble substance the absence of which in the diet of chickens causes the blood to become very slow in clotting. Thus far no evidence has indicated its importance for other species, although attempts to study the requirements of other species have been very limited.

The observations that led to this discovery were made by Dam³⁶ while attempting to determine whether hens could synthesize cholesterol. At this time he was feeding a synthetic diet composed of casein, starch, salt, marmite, filter paper and cod liver oil. In earlier studies, using a similar diet, he had observed subcutaneous and intramuscular hemorrhages as well as erosion of the gizzard. He had also noted that these chickens were anemic and that the number of erythrocytes was only about two million instead of three or more. In 1930 Horvath³⁷ also observed that the coagulation of the blood of chickens was accelerated by diets of sprouted soy beans.

The same hemorrhagic condition described by Dam was reported by McFarlane and his associates³⁸ in 1931 when they were attempting to establish the need of chickens for fat soluble vitamins. These workers were employing diets of about 70 per cent rice and 15 per cent marmite supplemented with various protein sources such as fish meal and casein. They suffered heavy losses from hemorrhage in chickens fed on a diet containing ether extracted fish meal but no losses if the fish meal was not extracted. Further, they found that blood from chickens fed this extracted fish meal could set in the laboratory over night without clotting.

In 1934 Dam and Schönheyder³⁹ found that this disease, which resembled scurvy in some respects, developed if chicks were fed cereals but that otherwise it developed even if the diet contained 15 per cent yeast. Neither lemon juice nor cevitamic acid alleviated the symptoms.

In the course of further studies it was found that the fats of hog's liver and hemp seed were rich in the factor while the fats from rye, sunflower, corn and rice had no effect. Cod liver oil was also without effect.

Dam and his co-workers⁴⁰ later found that the normal amount of prothrombin was lacking in chickens fed a diet deficient in vitamin K. The condition could be developed in about three weeks on a diet of casein 10, ether extracted pig's liver 10, dried yeast 15, sucrose 62.3, salt mixture 2.7 and cod liver oil 4. Three days after vitamin K is fed to deficient animals the blood becomes normal.

Rats and guinea pigs were fed a diet similar to that used for the chickens but no symptoms developed. A man suffering from hemophilia also yielded no response to the feeding of concentrates of the vitamin.

The factor was concentrated by Almquist¹¹ in 1936 so that 2 mg formed a sufficient supplement for 1 Kg of feed. This concentrate was prepared from a hexane extract of alfalfa. By distillation this material was concentrated still further. Under very low pressures the potent material could be distilled at from 120 to 140 C. This vitamin is unstable to alcoholic alkali and is unsaturated as well as colorless. It has no sulfur or phosphorus but a small amount of nitrogen. Color tests indicate an indole nucleus.

This vitamin seems to be synthesized by bacterial action, since its amount tends to increase in feedstuffs subjected to such action. The amount also increases in the feces of chicks on the deficient diet if these stand for a day. The diet of the hen may also influence the development of the disease in chicks.

About 1931 claims were made that vitamin A was concerned with the clotting of blood. As pure preparations became available, however, this was disproved. Recently, however, Schiff and Hirschberger¹² have found that there is some factor, which they term T, in egg yolk and sesame oil. This seems to increase the platelet count in both human and rat blood. They found that from five to ten drops of sesame oil per day or five egg yolks affords ample of this essential for treating children. It has also been claimed that semi-fasting dogs develop a severe thrombopenia and need this essential. Evidence is not clear that factor T and vitamin K are related.

The failure of blood to coagulate in "sweet clover disease" has long been recognized especially in young cattle that have consumed partly spoiled clover.¹³ Quick¹⁴ finds that this disease can be reproduced in rabbits. It is cured by feeding alfalfa. However, this disease is not related to the vitamin other than that alfalfa probably acts in furnishing materials for the synthesis of prothrombin. Hogan¹⁵ also observed that the ether extract of alfalfa prevented the hemorrhages of the nursing young in the case of rabbits.

It is well known that some fish meals are injurious to animals. Scott and Cook¹⁶ find that this injury is due both to the deficiency of vitamin K and to toxic factors in the fish meal. The toxic factor is chiefly reflected in the distorted blood picture with marked increase in lymphocytes and leukocytes.

GIZZARD EROSION FACTOR

The erosion of the gizzard was observed early in the studies of Dam. The question of whether or not this is due to a specific deficiency is still unsettled. Almquist and Stokstad¹⁶ found that it was cured by a saponifiable fraction of the hexane extract of alfalfa or

dried kale. Cod liver oil, wheat germ oil, orange oil, egg yolk and alfalfa ash failed.

Bird and his associates¹⁷ seemed to feel that the factor was specific but its properties, as far as solvent are concerned, conflicted with those found by Almquist. Thus the Wisconsin workers found the factor in such materials as pork lungs, liver and kidneys but they were not able to extract it with water, alcohol or ether. They found it to be labile to both dry heat and autoclaving at 120 C. Among the grains they found oats the best. In their hands alfalfa was not potent. Further studies will undoubtedly be needed to determine whether this is a specific factor.

VITAMIN P

Vitamin P is the term applied by Rusznayak and Szent-Gyorgyi¹⁸ to a substance that occurs in lemon juice and red peppers. In certain pathologic conditions characterized by increased permeability of the capillary wall, they found injection of concentrates to be effective when cevitamic acid failed. The early work indicated that the effective agent belonged to the vegetable dyes of the flavine group.

Workers from the same laboratory used guinea pigs that were fed a diet to produce scurvy. They found that these animals finally died of scurvy if fed the concentrate of vitamin P termed "citrim." However, these animals lived for about forty-four days, while the others lived only twenty-eight days.

In a later study Bruckner and Szent-Gyorgyi¹⁹ found citrim to be a mixture of hesperidine and eriodictyol glucoside and ascribed the activity and color to the latter. In unripe oranges they found much hesperidine but not much of the other compound.

The existence of this "vitamin P" has been questioned by Zilva.²⁰ He presents evidence which, as far as the experiments on guinea pigs are concerned, indicates that there is no reason for postulating a new factor. His work seems to show that the animals were suffering from vitamin C deficiency, which was relieved to a slight extent by contamination of the "citrim."

NICOTINIC ACID

From time to time nicotinic acid returns among the growth stimulants that resemble vitamins. Thus the Funk²¹ have presented evidence recently that the growth of rats and pigeons is stimulated by such derivatives. This work is interesting in the light of the need of staphylococcus for the same essential as a supplement to B₁ as reviewed by Kogl.²² Furthermore Elvehjem and his co-workers²³ have found that nicotinic acid will cure blacktongue in dogs. The workers have isolated considerable amounts of crystalline nicotine amide from active liver fractions. The effectiveness of this compound in the treatment of human pellagra has now been established and is discussed elsewhere.

TOXIC SUBSTANCES

The specific toxicities of various foodstuffs and the counter action of other vitamin-like components of the

diet cannot be neglected in a discussion of vitamins, although the subject material is too extensive for detailed consideration here. Throughout the literature on nutrition one is confronted from time to time with reports of toxicities from natural feedstuffs especially when they are fed in certain mixtures. A few of the products that can be recalled readily are linseed meal, cottonseed meal, wheat, corn, oats, clover, fish, fish liver oils and egg white. Even in the case of such a familiar product as linseed meal, in which the evidence is quite clear that a glucoside is the toxic agent, one who reviews the literature critically is aware of the many discrepancies involved. When one undertakes to analyze the various factors that interplay to protect or poison an animal with the cyanides from such products, the problem becomes more complex.

In recent years definite advances have been made in studying the neutralization of food toxins by vitamin-like substances in only a few cases.

In 1916 Bateman noted the toxicity of large amounts of egg white and the loss of this property after heating, acid denaturation and proteolytic digestion, according to Stepp and his associates.¹⁵ In 1927 Boas⁵³ found that rats suffered from dermatitis when the protein of the diet was supplied by certain forms of dried egg white. However, she learned that this disease could be cured if the wheat starch in the diet was replaced by potato starch. At the end of her first study she was uncertain whether she was dealing with a vitamin deficiency or a toxicity. Later she seemed to lean to a toxicity theory.

Parsons and her associates⁵⁴ have given special attention to this problem in recent years. They find that the toxicity of dried but uncoagulated egg white is rendered innocuous either by cooking, as observed by Boas, or by feeding substances such as dried yeast or dried liver. Furthermore, these workers report that the neutralizing factor is found in the organs of different species in different amounts. Human liver varies in its concentration of the factor while turkey liver is very rich.

The toxicity of fish liver oils is another field that has been studied during the past ten years. To Agduhr⁵⁵ must be given the credit for recognizing clearly that cod liver oil contained some factor that caused the degeneration of muscle tissue in herbivora. He also recognized from the beginning that this toxic factor of cod liver oil interplayed with other constituents of the diet. The ability of alfalfa to counteract partly this toxic property was recognized by Woodward and McCay.⁵⁶ Madsen and his co-workers⁵⁷ also found that this toxicity interplayed with the remainder of the diet. However, no diet was devised that would do more than delay the development of the degenerative changes. Later Madsen⁵⁸ found that cottonseed oil would partly

counteract this toxic factor of cod liver oil. Even in rats Norris and Church⁵⁹ found that yeast and cod liver oil interplayed in the diet. Instead of a sparing action on the B requirements by the fat of cod liver oil, they found that they must increase these B factors to obtain normal growth. This finding is especially interesting, since the rat is so immune to most food toxins compared to such species as guinea pigs. Recently Yamamoto⁶⁰ extended this study of the interplay between yeast and the toxic factors of cod liver oil.

This toxic factor of cod liver oil in the case of herbivora is shown in two ways: first, in degenerative changes in tissues and second, in lowering the secretion of the milk fat by a lactating cow. Limited evidence indicates that the toxic factor is the same in the two cases, according to the observations of McCay and Maynard.⁶¹ This factor is found in the saponifiable fraction and is probably an unsaturated compound, since hydrogenation of cod liver oil causes it to lose this toxic action. No explanation has been offered concerning the method by which such substances as alfalfa and yeast can react with an unsaturated fatty acid to remove its toxic action.

Hilditch and Thompson⁶² have produced evidence indicating that the unsaturated fatty acids of the C₂₀-C₂₂ series may account for part of the toxic action of cod liver oil. This is probably only part of the explanation, however, because salmon oil, which is rich in these same compounds, fails to produce the consistent effect of cod liver oil in lowering the secretion of milk fat. No mechanism has been devised to explain the interplay between dietary constituents in the case either of poisoning from egg white or of that from cod liver oil.

Finally a third field that has been given considerable attention in recent years is that concerned with the cerebellar disorder in chicks first discovered by Pappenheimer and Goettsch.⁶³ They found this to be produced in chicks fed a diet of milk powder, casein, starch, yeast, cod liver oil, salts and filter paper. In ducks fed a similar diet, injury to the muscles developed with no effect on the brain,⁶⁴ an observation of special interest because it shows that a science of nutrition cannot be grounded on one or two species such as the rat and the chicken. In later studies, vegetable oils, incorporated in the diet at 20 per cent levels, were found to afford complete protection in the case of chicks.⁶⁵

Jungherr and Pappenheimer have found more recently that turkeys respond to this diet in a still different manner. This species develops selective necrosis of the smooth muscle of the gizzard wall.⁶⁶

CONCLUSIONS

In such a review as this, which by its nature covers much of the vitamin literature that has not been amply confirmed, one must recognize that it will become obsolete in part, at least, by the time it is printed.

However, certain trends are clear. The science of nutrition is slowly extending to include more animal species. Each species that is included leads to the discovery of new vitamin requirements and specific reactions to mixtures of feedstuff. However, this broadening of the base must lead to a more complete science capable of providing generalizations with more certainty. Finally the need for better systems of naming new vitamins is obvious. The biologist who feeds animals must inevitably precede the chemist in the discovery of new essentials. The isolation of new factors is slow because these factors depend on biologic testing as well as involved technics. For this reason it is likely that there will be an increasing accumulation of vitamins awaiting the organic chemist. A better system of numbering them must be devised to prevent confusion in the period between their discovery and their isolation. Possibly some numbering system issued from a central office such as that of the League of Nations must be resorted to in the near future.⁶⁷

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED

FRANKLIN C BING Secretary

NUTRADIET SMALL WHOLE STRINGLESS BEANS PACKED IN WATER

Distributor—The Nutradiet Company, a subsidiary of S & W Fine Foods, Inc., San Francisco

Description—Canned beans packed in water without added salt or sugar

Manufacture—Blue Lake Stringless beans are inspected, snapped, again inspected, graded, inspected again, blanched, sprayed with cold water and packed into cans by hand. Hot water is added. The containers are sealed without exhausting. No. 2 cans are processed at 116° C for twenty-five minutes and cooled by the air injection method. Sometimes the vines are sprayed with nicotine insecticides. The packer believes that any spray residue is satisfactorily removed by the method of preparation. Not more than twenty-four hours elapses between the picking of the beans and the end of the canning process.

Analysis (submitted by manufacturer)—Moisture 95.6%, total solids 4.4%, ash 0.4%, fat (ether extract) 0.1%, protein (N × 6.25) 1.4%, crude fiber 0.4%, carbohydrates other than crude fiber (by difference) 2.1%

Calories—0.15 per gram, 4 per ounce

Claims of Manufacturer—For use in special diets in which sugar or salt is proscribed or in quantitative diets of calculated composition

STEPHENS BRAND PURE LEMON JUICE

Manufacturer—Natural Food Products Company, Orange, Calif

Description—Canned lemon juice

Manufacture—Tree ripened lemons, on which no arsenical sprays are used, are washed, dried, inspected, cut in half and the juice removed. The juice is sieved, deaerated and then subjected briefly to ultraviolet rays to inactivate "enzymes" and to reduce the bacterial count. The finished juice is filled into cans, sealed under high vacuum, pasteurized and cooled.

Analysis (submitted by manufacturer)—Moisture 89.9%, total solids 10.1%, ash 0.4%, fat (ether extract) 0.1%, protein (N × 6.25) 0.5%, crude fiber 0.01%, nonreducing sugars as sucrose 0.05%, reducing sugars as invert sugar 1.58%, carbo-

hydrates other than crude fiber (by difference) 2.3%, titratable acidity as citric acid 6.85, specific gravity 20/20° C, 1.0, vitamin C (iodine titration) 59 mg per hundred cubic centimeters (1,200 international units)

Calories—0.1 per gram, 3 per ounce

Vitamins—The product contains 355 international units of vitamin C per fluidounce

MULKEY'S THE ORIGINAL "IODINE" SALT

Distributor—Mulkey Salt Company, Detroit

Description—Table salt containing 0.023 per cent of potassium iodide and 1 per cent of magnesium carbonate

Manufacture—Pure water is pumped down through typical salt well casings to the salt deposit, where it forms a brine which is brought to the surface and evaporated. The sodium chloride crystallizes out and is washed with pure brine, kiln dried and the crystals are screened to uniform size. The salt is mixed with magnesium carbonate, which tends to keep it free running. The iodine is added by weighing out on an accurate scale a high concentration of potassium iodide sodium chloride mixture. Following the addition of this mixture the final mixture is compounded, packed in special cartons and sealed.

Analysis (submitted by manufacturer)—Calcium chloride, trace, calcium sulfate 0.31%, sodium sulfate, trace, magnesium carbonate 0.62%, sodium carbonate 0.10%, potassium iodide 0.023%, sodium chloride (by difference) 98.9%

BORDEN'S CHATEAU PIMIENTO

Manufacturer—The Borden Company, New York

Description—Mixture of Cheddar cheese, cream, skim milk powder, pimiento, water, disodium phosphate, sodium chloride sodium citrate, citric acid and annatto

Manufacture—The manufacture is essentially the same as that described for Borden's Chateau (THE JOURNAL, March 20, 1938, p. 958) except that pimiento peppers are added to the Borden's Chateau mix immediately before pasteurization.

Analysis (submitted by manufacturer)—Moisture 39.5%, total solids 60.5%, total ash 5.0%, sodium chloride (NaCl) 1.9%, fat (ether extract) 31.1%, protein (N × 6.38) 21.7%, lactose (by difference) 2.7%

Calories—3.78 per gram, 107 per ounce

Vitamins—An excellent source of vitamin A and contains vitamins B and G

CARNATION FLOUR

Manufacturer—Kell Mill & Elevator Company, Wichita Falls, Texas, a wholly owned subsidiary of General Mills, Inc., Minneapolis

Description—Hard-wheat patent flour designed for general baking purposes

Manufacture—Hard wheat is cleaned, scoured, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18, 1932, page 2210. Chosen flour streams are blended and bleached with a mixture of benzoyl peroxide and calcium phosphate (1 part to 50,000 parts of flour) and nitrogen trichloride (1.5 to 3 Gm per 196 pounds)

Analysis (submitted by manufacturer)—Moisture 13.0 to 14.5%, total solids 87.0 to 85.5%, ash 0.38 to 0.42%, fat (ether extraction method) 0.8 to 1.2%, protein (N × 5.7) 10.0 to 12.0%, crude fiber 0.3 to 0.5%, carbohydrates other than crude fiber (by difference) 75.5 to 71.4%

Calories—3.4 to 3.5 per gram, 97 to 99 per ounce

APPELLA APPLE POWDER (STEARNS)

Distributor—Frederick Stearns and Company, Detroit

Packer—Appella Corporation, Seattle

Description—Powdered dried apple pulp. A blend of products produced from several varieties of apples selected for their high content of pectin and uronic acids the same as Appella Apple Powder (THE JOURNAL, Nov. 13, 1937, p. 1637)

REPORTS OF OFFICERS

NOTE—At the 1925 session of the Association, the House of Delegates suggested that all reports of officers, committees, etc., and resolutions to be brought before the House, if available, be published in advance of the session so as to permit careful consideration and discussion—Ed

REPORT OF THE SECRETARY

To the Members of the House of Delegates of the American Medical Association

The following annual report of the Secretary is respectfully submitted

MEMBERSHIP

On April 1, 1938, the number of members enrolled was 109,435 as compared with 105,460 on the corresponding date in 1937. This enrolment, larger by several thousand than in any preceding year, is based strictly on official reports submitted to the Secretary of the American Medical Association by the secretaries of the constituent state and territorial medical associations. The state and territorial associations do not follow a uniform rule with respect to the removal of names of members whose dues may be in arrears. In some instances constituent associations have dealt rather leniently with those members whose dues have not been promptly paid, apparently because of the effect on a considerable number of members of the existing economic situation. In some states the membership year strictly corresponds with the fiscal year, while in others the names of members in arrears are continued on official lists for varying periods of time. It is therefore probable that the number of members as here recorded will be reduced to some extent because of the removal of names of members from constituent association lists after April 1.

Increases in membership are shown for thirty-nine of the fifty-four constituent state and territorial associations, while decreases are shown for fourteen. One state association shows the same number of members in 1938 as in 1937. The largest decrease in membership in any constituent association was fifty-four, while losses shown in others varied from one to fifty. The largest increase in membership was shown in New York, with 1,033 new members recorded, and the next largest was in Ohio, with an increase in membership of 738. While it is difficult to determine the exact facts, it is estimated that from 75 to 80 per cent of the total number of eligible physicians engaged in private practice are recorded as members of the American Medical Association.

FELLOWSHIP

The number of Fellows as shown by the official Fellowship roster on April 1, 1938, was 68,478 as compared with 66,296 enrolled on the corresponding date in 1937. This establishes a new Fellowship record. An accompanying table shows the number of counties in each state and territory, the number of component societies as shown by the records in the Secretary's office, the number of members enrolled in the state and territorial associations and the number of Fellows in each state and territory, including commissioned officers of government medical services.

BETTER ORGANIZATION

It is quite evident that a much greater interest is now being taken in the affairs of medical organization than at any previous time since the reorganization of the American Medical Association in 1902. This is clearly shown by the fact that there has been a very decided increase in the number of enrolled members and is even more definitely shown by the tremendous growth of correspondence pouring into the offices of the Association. County medical societies in all parts of the country are carefully studying their organic laws and in a great many instances improving amendments to the constitutions and by laws have been made in the past year. A number of state medical associations have amended their constitutions and by laws or are contemplating amendments, with a view to increased efficiency.

There is a constantly growing tendency in constituent state associations and in the larger component county medical societies toward the employment of full-time secretaries or of full-time executive secretaries, to the end that official matters may be more promptly and efficiently handled. The councils and com-

mittees of state medical associations and of a large number of county medical societies are now holding regular meetings at stated intervals and are giving most careful and thorough consideration to matters that properly come before such bodies for official action. In several states the officers and members of official bodies of constituent associations have officially visited

all the county societies within their respective jurisdictions, while in other states such visits have been made to all counties in which meetings could be arranged. The attendance of presidents and other representatives of state medical associations at the Annual Conference of Secretaries of Constituent State Medical Associations held at Association headquarters in Chicago each year is increasing. There are many other indications of increased efficiency on the part of constituent associations and component societies. However, while there is just cause for gratification, it must be regrettably admitted that there is still great need for better organization and increased efficiency in many places.

In some instances interest in the scientific work of county medical societies is apparently lagging to an unfortunate degree. There is good reason to believe that this may be due to the fact that the scientific programs of such societies have become static and have been largely confined to the discussion of a limited range of subjects. In other instances it is quite possible and even probable that the scientific functions of county medical societies have been given over to other groups, even though the official membership of such groups largely corresponds with the membership of the societies themselves. On the other hand the scientific work of a number of the state associations and of a much larger number of county medical societies is being vigorously prosecuted and is generously supported by the general membership. There is a decided tendency toward the development of scientific programs of a nature far different from those that have usually been presented. There seems to be a desire on the part of a great many physicians to have the scientific programs place especial emphasis on the purely clinical aspects of medical practice, and it would seem to be the part of wisdom for the officers and members of program committees to give careful thought to the possibility of making changes that may be necessary to awaken and to hold the continued interest of their members.

FIELD WORK

The demand for the services of members of the official and administrative personnel of the Association as speakers before scientific and lay groups has increased to such an extent that it has been altogether impossible to meet it fully, though the number of such appearances was far greater in 1937 than in any preceding year.

Several constituent state medical associations have organized bureaus for the purpose of providing speakers, and these bureaus have received splendid cooperation that has enabled them to meet most of the requests for speakers.

The American Medical Association, a few of the state associations and a considerable number of county medical societies have, with the cooperation of broadcasting companies and individual stations, conducted radio programs that have been heard by many listeners in all parts of the United States. Many of the state and county medical societies, through official committees, have maintained helpful contacts with civic and official organizations interested in public health.

PROPOSED AMENDMENTS TO THE CONSTITUTION

At the annual session of the Association held in Atlantic City in 1937, the Judicial Council submitted the following resolution:

WHEREAS The Constitution and the By Laws refer to the election annually of a President and President Elect when in fact only a President Elect is elected and

WHEREAS No provision is made in the Constitution and By Laws for a succession in office in case of death or disability of the President Elect be it

Resolved That article 6 section 2, of the Constitution be amended to read (a) The President Elect shall be elected annually. He shall serve as President Elect until the annual session of the Association next ensuing after his election and shall become President on his installation in the course of that session serving thereafter as President until the next following annual session and the installation of his successor. If the President Elect dies resigns or in the judgment of the Board of Trustees confirmed by the House of Delegates is permanently disqualified for the performance of the duties of his office by any just cause the Vice President shall become President Elect and in due course succeed to that presidency with all of the prerogatives and duties pertaining to that office as fully as if elected to it in the first instance. Provided however that the President Elect who is elected at the annual session of the Association in 1937 shall notwithstanding his election as such for the period of one year only be installed as President in the course of the session in 1938 and continue as such until the session in 1939 and the installation of his successor.

(b) A Vice President a Secretary, a Treasurer and a Speaker and a Vice Speaker of the House of Delegates shall be elected each to serve for one year and until his successor is elected and installed. Provided however that in event of the death resignation or removal or of the permanent disability of the President Elect as determined by the Board of Trustees the Vice President shall succeed to the office of President Elect and in due course to the office of President notwithstanding the fact that he was in the first instance elected as Vice President for one year only.

This resolution received the consideration of the Reference Committee on Amendments to the Constitution and By Laws. The following report was submitted to the House of Delegates by the Reference Committee and was adopted, after which the Speaker of the House ruled that the proposed amendment would lie over for one year to receive official consideration at the annual session in 1938.

The resolution to amend the Constitution dealing with the election of the President and President Elect of the Association introduced by Dr. George Edward Follansbee, Chairman, Judicial Council has received consideration at the hands of your committee.

Since this is an amendment to the Constitution it will have to lie over for a period of one year before final action can be taken by this House.

The purport of the amendment to the present Constitution is to make better provision for succession in office in case of death or of disability of the President Elect. In giving consideration to this important matter your reference committee feels that this body might take under advisement the possibility of providing by constitutional amendment a Vice President Elect to be included in the general officers of the Association. Such provision is not made in the present Constitution nor does the proposed amendment make such provision. Such provision would necessitate the amendment of Section 1 of Article VI of the Constitution by including a Vice President Elect as one of the general officers of the Association as well as making certain alterations in the phraseology of the proposed amendment.

No resolutions intended for presentation to the House of Delegates have been sent to the Secretary's office up to the time of the preparation of this report.

Most grateful acknowledgment is here made of the helpful kindnesses that have been extended to the Secretary by members of official bodies of the Association, including the House of Delegates, by secretaries and other officers of constituent state and territorial associations and of component county societies, and by a large number of the individual members of the Association.

Respectfully submitted

OLIN WEST, Secretary

REPORT OF THE BOARD OF TRUSTEES

To the Members of the House of Delegates of the American Medical Association

Death of Dr. George H. Simmons

Dr. George H. Simmons, Editor and General Manager Emeritus, died in Chicago on Sept. 1, 1937. The following resolution, in which the great service rendered by Dr. Simmons to American medicine is set forth was officially adopted by the Board of Trustees and spread on its minutes:

WHEREAS Dr. George H. Simmons rendered distinguished service to the medical profession and to the American Medical Association from 1899 when he became Secretary and Editor through 1924 when he retired holding the positions of Editor and General Manager, and

WHEREAS During this period of twenty five years his wise leadership his courage his progressiveness and his initiative advanced the interests and the status of the Association to heights never before reached by any medical organization and

WHEREAS His work for the American Medical Association was characterized by intelligence unselfishness honesty and righteousness and his interest endured to the very end of his days and

WHEREAS The Board of Trustees through its intimate contact with Dr. George H. Simmons in all of these works is cognizant of the extent to which he gave of himself freely for the good of all therefore be it

Resolved That this Board of Trustees spread upon its minutes its recognition of his accomplishment and that it tender to his relatives suitable copy of these resolutions and its sincere sympathy in their sorrow at his passing.

The General Work of the Association

The year covered in this report of the Board of Trustees has been characterized by a very notable expansion in the activities of the various councils, bureaus and departments of the Association until, at times, available facilities have been seriously strained. A constantly growing interest on the part of the general membership in changing social conditions

increased efficiency of medical organization in counties and states throughout the nation, a more active and intelligent interest on the part of the public in matters pertaining to public health and medical service, legislative activities in the states and in the federal government the consideration of important questions pertaining to medical education, hospital operations and the extension of public health programs, greater financial and administrative participation on the part of the federal government in public health affairs in states and in communities, proposals for the development of medical and hospital service plans for the benefit of the members of low income groups and actual operation of such plans and a notable increase in the number of members of the Association together with many other important factors have brought into the headquarters offices a veritable flood of inquiries and demands for information and service. An earnest effort has been made to meet such demands as fully and as helpfully as possible.

Business Operations

The official Report of the Treasurer and the official Report of the Auditors are submitted to the House of Delegates as a part of this report of the Board of Trustees.

The gross earnings for the year ended Dec 31, 1937, amounted to \$1,654,203.74 as compared with \$1,547,218.23 in 1936. Operating expenses were \$982,830.10 as compared with \$909,417.95 in the preceding year. Association expenses including expenditures incident to the operations of councils, bureaus and departments amounted to \$431,635.63 as compared with \$411,028.93 in 1936, while miscellaneous expenses for the year 1937 including insurance and taxes, building expenses and depreciation, fuel, legal services and the cost of sundry publications amounted to \$218,601.19 as compared with \$209,382.37 in 1936. The net income for the year was \$122,242.92, of which sum \$83,563.74 represented income from investments, so that the actual net operating income was \$38,679.18.

While only a few of the bonds owned by the Association have defaulted in the payment of interest, there has been a rather serious depreciation in the market value of some of the securities held. The Board of Trustees, the Treasurer and the General Manager of the Association have sought the best available advice with respect to investment of the Association's funds. In accordance with the situation that generally prevails, the average interest return on invested funds has been decreased because of the substitution of securities bearing lower interest rates than those which formerly obtained.

The payment of wages and salaries, exclusive of those involved in the operation of councils and bureaus amounted to \$460,182.01 in 1937 as against \$443,693.17 in 1936. Increased labor costs in effect during the latter part of the year accounted for most of the increase in this item, and notification has already been received to the effect that these costs will be further increased during the current year. The cost of paper in 1937 was \$241,663.85 as compared with \$208,922.37 in the preceding year. These costs would have been considerably larger except for the fact that the fullest possible advantage was taken of the opportunity to purchase paper stock before material increases in the market price went into effect. The sum of \$97,274.89 was expended for postage in 1937 as against \$92,123.08 in 1936.

Fellowship dues and subscriptions paid in 1937 amounted to \$670,170.31 as compared with \$638,243.18 in 1936 the increase being due principally, to increased circulation of THE JOURNAL and to a rather notable increase in the number of Fellows enrolled. Total receipts from the sale of advertising space in Association publications were \$841,042.57 as against \$780,299.01 in 1936.

The number of employees at the time of the preparation of this report was 616.

The purchase of some new machinery and equipment contemplated when the last annual report of the Board of Trustees was submitted to the House of Delegates was deferred in part for the reason that some of the machinery that must be purchased will have to be newly constructed and in part because some of the older machinery which it had been intended to discard was repaired or partially rebuilt so as to extend its usefulness. It will be necessary to install some new machinery in the printing department during the current year.

Increased activities of the councils, bureaus and departments of the Association have required the purchase of a considerable amount of new office material.

In the Report of the Treasurer and in the Report of the Auditors submitted herewith will be found more fully itemized statements of income and expenditure.

Summary

Gross earnings and miscellaneous income were larger in 1937 than 1936, while operating and miscellaneous expenses were also considerably larger. Income from investments was slightly larger than in 1936. The net income for the year was \$122,242.92, of which amount \$83,563.74 represented interest on investments and \$7,453.20 represented miscellaneous income.

The Association Building

The experience of the past year has fully justified the action taken by the Board of Trustees whereby the entire building was remodeled and two new stories and an assembly hall were added. Better working conditions have been afforded in all departments, and it has been possible by reason of building expansion to bring closer together councils and bureaus whose work is closely correlated and thereby to avoid unnecessary duplication of effort and to increase efficiency.

Many commendatory expressions have been received concerning the beauty of the Association's building as it now stands. The Board of Trustees would urge the members of the House of Delegates and the members and Fellows of the Association who may find opportunity to do so to visit the headquarters offices to see at first hand the nature and the scope of the work that is being prosecuted there.

The Journal of the American Medical Association

The place held by THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION in the field of medical periodicals is now so well established that it is unnecessary to offer comment on this point. Nevertheless, the publication has not been static. It has developed a new series of articles on the relationship of the pharmacist and the physician. It has continued its campaigns against mortality from typhoid and from diphtheria and has reestablished the campaign against Fourth of July accidents.

The publication formerly called the BULLETIN OF THE AMERICAN MEDICAL ASSOCIATION is now fully incorporated in THE JOURNAL as the Organization Section. Here special attention is given to problems of organization, to medical economics to reports of activities of various councils, bureaus and departments, and to the work of the Woman's Auxiliary. The value of this week by week circulation of important information in the field of economics and of organization for the maintenance of interest of the individual physician cannot be overestimated. Because of the significance of this material, the Board of Trustees would recommend that it be placed in the center of THE JOURNAL and incorporated as a regular feature on medical economics.

Attention should be called in this connection to the arrangements that have been made whereby officials of the British Medical Association contribute regularly important statements as to medical economic conditions in Great Britain and as to the manner in which the British Medical Association is attempting to solve its problems.

Especially noteworthy among the features of 1937 was the exposure of the cause for the deaths of more than seventy persons who had taken an elixir of sulfanilamide. The prompt exposure of new methods of treatment of cancer not fully established and the regular reports of the Council on Pharmacy and Chemistry, the Council on Foods and the Council on Physical Therapy serve to protect both the public and the medical profession against unestablished and even fraudulent methods of treatment as well as to keep the medical profession abreast of what has been fully established in these fields.

During the year the series of articles on The Therapy of the Cook County Hospital has been continued so that even

tually the complete series will be available in book form. Special issues of THE JOURNAL have been devoted to hospitals, to medical education and to the state licensing boards as well as to the annual session. Each of these special issues has been the means of extending widely the work carried on by the Association for the raising of standards of medical education.

In the campaign of the United States Public Health Service for the control of pneumonia, THE JOURNAL cooperated by conducting a survey of hospitals in the United States as to the facilities for the typing of pneumococci and by prompt publication of the available material for the education of the medical profession in modern methods of diagnosis and treatment.

A feature of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION not duplicated in any other medical publication in the world is the department of Queries and Minor Notes. Each year some 5,000 questions are submitted to this depart-

received are referred for reply to physicians recognized as authorities in the fields concerned. Many of the questions are answered from available medical literature, some of them answers already published and many by personal communication, usually supplemented with material from the library of the American Medical Association. Approximately 40 per cent of the questions come from physicians in communities where

* This table gives the number of physicians (based on the Fourteenth Edition of the American Medical Directory) in the United States the number receiving THE JOURNAL and the approximate percentage in each state. Copies to physicians in the United States Army and Navy are not included.

adequate library facilities are available, the remainder from communities without opportunities for such consultation.

The accompanying table 1 indicates the number of Fellows and subscribers on the mailing list of THE JOURNAL, by states on Jan. 1, 1938, and the gain or loss. Table 2 shows the percentage of physicians receiving THE JOURNAL in each state the figures being based on the Fourteenth Edition of the American Medical Directory.

The circulation of THE JOURNAL on Jan. 1, 1938, was 977,100 as compared with 94,180 Jan. 1, 1937. The net paid circulation Jan. 1, 1938, was 96,812.

Summary

Continued effort has been made to increase the usefulness of The Journal. New features include the development of a series of articles on the relationship of the pharmacopeia and the physician. Campaigns against mortality from typhoid and from diphtheria and against Fourth of July accidents have been reestablished.

The publication formerly known as the Bulletin of the American Medical Association is now fully incorporated in The Journal as the Organization Section. In this section special attention is given to problems of organization, to medical economics, and to the activities of various councils, bureaus and departments and the Woman's Auxiliary.

ment by physicians who wish information regarding the diagnosis, treatment or handling of individual cases, an official opinion on the new drugs and new procedures, information regarding industrial poisons, discussions of disease, advice regarding new laboratory methods or specific references to the available literature. About 20 per cent of the questions

Arrangements have been made whereby officials of the British Medical Association contribute regularly statements concerning medical economic conditions in Great Britain and the manner in which the British Medical Association is attempting to deal with such matters.

The prompt publication in *The Journal* of all the facts concerning the disastrous results of the use of the product known as Elixir of Sulfanilamide, the prompt expose of newly promoted methods of treatment of cancer not fully established, and regular reports of the Council on Pharmacy and Chemistry, the Council on Foods and the Council on Physical Therapy have attracted wide attention and have served to protect the public and the medical profession against unestablished and even fraudulent methods of treatment.

The series of articles on the Therapy of the Cook County Hospital has been continued, and these articles will eventually be made available in book form.

Special issues of *The Journal* have been devoted to medical education, to hospitals and to the activities of state licensing boards. Each of these special issues has been helpful in extending the work carried on by the Association for the improvement of standards of medical education.

The *Journal* has cooperated with the United States Public Health Service in the campaign to establish better control over pneumonia. A survey was made of the facilities available in the hospitals of the United States for the typing of pneumococci, and available material concerning modern methods of diagnosis and treatment of pneumonia has been promptly published.

An important feature of *The Journal* is the department devoted to Queries and Minor Notes. Approximately 5,000 questions are submitted by physicians each year. These questions cover a wide range of subjects. While most of them are answered by members of the official staff of the Association, about 20 per cent are referred for reply to physicians recognized as authorities in the fields concerned. Approximately 40 per cent of such inquiries come from physicians in communities where adequate library facilities are available, and the remainder from physicians in communities without opportunities for such consultation.

Special Journals

The eight special periodicals published by the Association have been maintained at their usual high standards of previous years, both scientifically and mechanically. The number of pages of reading matter varied but slightly over the preceding year, but there was an increase of fifty in the number of pages of advertising carried. Five of the journals showed an increase of seventy-two pages of advertising matter, while three showed a decrease of twenty-two pages.

The January 1937 issue of the *ARCHIVES OF DERMATOLOGY AND SYPHILOLOGY* was dedicated to Dr. William Allen Pusey, who retired from the Editorial Board at the close of 1936 after having served as Editor in Chief for seventeen years. The articles in this issue were contributed by physicians and laymen who had been associated with Dr. Pusey in various capacities.

The April 1937 issue of the *ARCHIVES OF NEUROLOGY AND PSYCHIATRY* was dedicated to Dr. Adolf Meyer in honor of his seventieth birthday and as an expression of appreciation for his service to psychiatry and to American medicine. This issue contained 272 pages of articles contributed by Dr. Meyer's former pupils. He has served as a member of the Editorial Board of the *ARCHIVES OF NEUROLOGY AND PSYCHIATRY* for approximately ten years.

A supplement to the January 1937 issue of the *AMERICAN JOURNAL OF DISEASES OF CHILDREN* was published and contained two articles on basal metabolism comprising 156 pages.

The Board of Trustees has carefully considered requests that the Association undertake the publication of several independent journals devoted to special fields of medicine but has not been able to comply with these requests. The Board of

Trustees has considered it inadvisable to permit any of the periodicals published by the Association to be known as the official organ of any specialistic medical society. Requests for a reconsideration of this decision have been received, but up to this time no evidence has been submitted to convince the Board of Trustees that its official attitude should be changed.

The cost of publication of the special scientific journals over income received was \$25,958.37. Only two of the publications in this group produced income larger than production costs. The loss thus sustained was less by the sum of \$7,862.93 than in 1936.

While it seems probable that it never will be possible to publish the special journals without financial loss, the Board of Trustees has believed, and apparently has been supported by the House of Delegates in this belief, that these publications constitute a distinct contribution to scientific medical literature and that the cost involved is fully justified by that fact. However, there is a limit beyond which, in the opinion of the Board of Trustees, it would not be wise to go in the continued absorption of yearly losses. Some of the special journals have encountered competition because of new publications fostered by special groups and published by commercial organizations. In some instances these competing periodicals, though they have been made official organs of special groups whose members are members and Fellows of the American Medical Association, have accepted advertising matter of a kind that is not acceptable for the Association's publications.

All the special journals had a larger circulation in 1937 than in 1936, but in no instance was the increase as large as it should be in view of the excellence of scientific material presented in these publications.

Summary

The special journals of the Association have been maintained at their usual high standards. While the total circulation of this group of periodicals was larger in 1937 than in the previous year, the increase was not as large as would be fully justified by the quality of the scientific material presented.

New publications in the same fields as those covered by some of the special journals have been established within the last few years as the official organs of special societies.

The loss incurred through the publication of the special journals in 1937 was \$25,958.37, as compared with a loss of \$33,821.30 in 1936. Only two of the journals produced incomes larger than production costs.

Library and Quarterly Cumulative Index Medicus

Throughout the country, the Library of the American Medical Association has come to be recognized as one of its greatest assets and as one of the chief facilities for rendering to the medical profession a service of the utmost importance in relationship to graduate education and the practical application of medical care. The services of the Library include the compilation and editing of the *QUARTERLY CUMULATIVE INDEX MEDICUS*, the package library service, the periodical loan service, the indexing of *THE JOURNAL* and the usual services rendered by a reference library.

The work of the *QUARTERLY CUMULATIVE INDEX MEDICUS*, which is everywhere recognized as one of the greatest contributions of the American Medical Association to medical research and the advancement of medical science, has now become systematized so that it is carried on regularly in a routine manner. The circulation of the *QUARTERLY CUMULATIVE INDEX MEDICUS* was approximately 6 per cent larger in 1937 than in the preceding year but the total income from sales of this publication is far below the amount required to equal the costs of preparation and publication. In 1937 expenditures exceeded income received through subscriptions to the *QUARTERLY CUMULATIVE INDEX MEDICUS* by the sum of \$42,616.32, slightly more than in 1936 but less than the losses shown in 1934 and 1935. The production of the *QUARTERLY CUMULATIVE INDEX MEDICUS* is an essential activity of the Association and deserves far more liberal support than it is receiving from individual physicians and medical institutions.

More than 1,400 periodicals are regularly received in the Library and are available for indexing and for reference purposes. As a result of the war in Spain, practically no scientific Spanish periodicals have been received during 1937, and those are omitted from the index for that year. As a result of significant changes in the periodical literature of Central Europe, scientific medical material available for indexing is less in amount and apparently of a different quality.

Because of the popularity of the package library service, the rule requiring written requests for material has been strictly enforced. All requests are handled in order of receipt, regardless of whether the physician is a resident of Chicago or of Seattle. The number of packages requested is approximately the same as in previous years. Altogether, 3,014 packages were distributed during 1937. The subjects called for indicate the trend of medical progress and scientific interest. The leading subjects include dementia praecox, alcohol and alcoholism, arthritis, pneumonia, sulfanilamide, undulant fever and the progress of medicine.

The periodical loan service continues to be exceedingly popular, since it makes available to practitioners everywhere the original reference material to which attention may have been called by the indexes and the abstracts. Members and subscribers requested 10,759 periodicals during 1937. Moreover, the Library answered about 6,200 general reference questions and telephone inquiries during the year. Notwithstanding the fact that the facilities for the use of the Library by visitors are not extensive, 1,262 physicians called in person during 1937 to obtain the services of this department.

The Library also conducts a subsidiary department devoted to the circulation of reading material for employees of the Association. During the year, 5,220 books were borrowed by employees, with an average daily circulation of twenty-one books.

Summary

The services of the Association's Library include the compilation and editing of the Quarterly Cumulative Index Medicus, the package library service, the periodical loan service, indexing of The Journal and the usual services rendered by a reference library.

More than 1,400 periodicals are regularly received in the Library and are available for indexing and for reference purposes. Because of the war in Spain, very few Spanish periodicals were received during the last year and scientific medical material available for reference and for indexing from Central Europe has been less in amount than heretofore and apparently of a different quality.

The Quarterly Cumulative Index Medicus, recognized as one of the greatest contributions of the Association to the advancement of medical science, had wider circulation in 1937 than in the previous year, but the cost of publication exceeded income received from subscriptions by the sum of \$42,616.32, slightly more than in 1936 but less than in 1934 and 1935. This publication represents an essential activity of the Association and deserves far more liberal support than it now receives.

More than 3,000 library packages were distributed during the year and nearly 11,000 periodicals were lent to physicians through the periodical loan service. The Library answered more than 6,000 general reference questions, and though the facilities for the use of the Library by visitors are not extensive, more than 1,200 physicians called in person during the year to obtain the services of this department. Through the Employees' Library 5,220 books were made available for the use of the working personnel of the Association.

Standard Classified Nomenclature of Disease

During 1937, by action of the Board of Trustees the editorial department of the American Medical Association took over the publication and the correspondence incident thereto of the Standard Classified Nomenclature of Disease—a cooperative effort formerly subsidized by the Commonwealth Fund. This editorial function has been placed under an assistant editor

Dr Edwin P. Jordan. The demand for the work since it has been taken over by the Association was so great that it was necessary to reprint promptly the available edition of this work, which is gradually being adopted by more and more hospitals as a means of preparing standard indexes of case records. The recommendation has been received for publication at some future date of a supplement to this standard nomenclature containing a standard nomenclature for surgical operations. It has also been proposed to undertake cooperative effort with the Bureau of Census so as to secure some uniformity of the nomenclature of disease with the international list of causes of death. The recommendation is also made to the Board of Trustees and to the House of Delegates for a conference to be held in the headquarters office of the American Medical Association in 1940 to which all the scientific societies which cooperated in the development of the present nomenclature will be invited to send representatives preliminary to the publication of a new edition of this work.

Hygeia

The circulation of *HYGEIA*, the Health Magazine, published by the American Medical Association, reached during 1937 the highest figure in its history, after fifteen years of continuous publication. A comparison of the present publication with the numbers issued during 1923 indicates the great progress that has been made in the development of this periodical from the point of view of its typography, illustrations and the quality of the material contained. More and more the special appeal of *HYGEIA* as a periodical useful in the schools has become apparent. Moreover, a special section has been developed to correlate the radio program of the American Medical Association (now directed primarily to the schools) with the text material available through *HYGEIA*. Of particular importance as new features in this publication are the series of articles on vision and light, on quackery and its methods, on parasites that affect human beings, and on hygiene—both personal and public. Another feature introduced during 1937 and now developing much acclaim is the teaching of health through pictures, each issue of *HYGEIA* now containing from four to six pages of pictorial education regarding the human body in health and in disease. The questions and answers regularly published in *HYGEIA* and the communications received from its readers are evidence of the place that it has come to occupy in its field.

Summary

While there was a gain in the average monthly circulation of *Hygeia* in 1937, publication costs exceeded income by the sum of \$31,004.90, largely because of the difficulties encountered in maintaining circulation. The advertising income in 1937 was larger by the sum of \$4,629.29 than in 1936.

Improvements have been made in typography and illustrations as well as in the quality of reading material.

A section has been developed to correlate the Association's radio program with the text of *Hygeia*.

Cooperative Medical Advertising Bureau

Commissions earned by the Cooperative Medical Advertising Bureau which represents thirty-three of the official publications of the constituent state medical associations, amounted to \$30,681.91 in 1937. Of this amount the sum of \$15,099 was remitted to the state medical journals. Advertising contracts secured through the Bureau for the state journals in 1937 amounted to \$156,705.47.

Mr. E. W. Mattson, after having served most efficiently as director of this Bureau for twenty-four years, retired from active service on Dec. 31, 1937.

Summary

The earnings of the Cooperative Medical Advertising Bureau in 1937 were \$30,681.91. Of this amount, \$15,099, almost 50 per cent of the total earnings, was remitted to the state journals. The amount involved in advertising contracts secured by the Bureau was \$156,705.47.

Mailing and Order Department

The total number of orders passing through the Order Department in 1937 was 68,282, and the total number of units distributed as a result of these orders was 474,483. The greatest demand was for material issued through the Bureau of Health and Public Instruction, and the next greatest demand during the year was for material prepared by the Bureau of Medical Economics.

In handling the orders referred to nearly 6,000 mail bags were used with a total weight of 174 tons.

Slightly less than 400,000 pieces of first class mail and more than 1,000,000 pieces of third class mail passed through the Mailing Department in 1937.

The Motion Picture on Syphilis

Through a cooperative effort of the American Medical Association with the United States Public Health Service, a seven reel talking motion picture on "Syphilis" was made available during 1937. In the development of this picture to be used in graduate education regarding syphilis, the following physicians participated:

Executive Committee: Drs. Morris Fishbein, Austin A. Hayden and Olin West.

Participating in the picture: Drs. Charles Gordon Heyd, Thomas Parran, John H. Stokes, Harold N. Cole, Paul O. Leary, James R. McCord, Philip C. Jeans, Joseph E. Moore and R. A. Vonderlehr.

During the year the picture was circulated widely among county and state medical societies and in medical schools. Extra copies were purchased by the United States Public Health Service and by health departments of several states. The success of this film is an indication of the possibilities in this method of graduate education for the future.

The text of the film has been reproduced in pamphlet form as a means of extending the information provided in the film itself.

The Conference on Publicity for Scientific Medicine

By direction of the Board of Trustees a conference was held during 1937 in the headquarters office of the American Medical Association on the provision of adequate publicity for medical science. This conference was attended by representatives of the leading press services, newspapers and periodicals of the United States as well as by writers of syndicated columns on health. This interchange of opinions and experiences served to bring out some of the difficulties inherent in the securing of adequate publicity for medical science as a means of educating the public regarding progress in medicine and the motives of the medical profession. The complete report was published in the Organization Section of *THE JOURNAL*. Its reception by the medical profession indicated so much interest that the Board of Trustees plans a similar conference in the future.

Books Published by the American Medical Association

During 1937 there became available in addition to the publications of the various councils the eleventh edition of the *Handbook of Therapy*, published by the American Medical Association.

There also appeared in book form a translation into German of the volume on *Glandular Physiology and Therapy*.

The Editorial Department has also been active in developing a book on *Medical Writing* and a new edition of *The Technique of Medication*.

Retirement Fund

From time to time it has become necessary for members of the Association's administrative personnel to retire from active duty after years of devoted and efficient service and for the Association to provide retirement pay for some of those who have thus been placed on the inactive personnel list. Believing that it is the duty of the Association to make provision for the comfort and well being of those who have rendered long and

valuable service to the Association and who have not been able to provide a competency for their use in their declining years, the Board of Trustees has taken official action whereby the sum of \$25,000 will be set aside each year until an adequate amount has been accumulated, the fund thus established to be known as the Retirement Fund and to be used for the benefit of employees who because of increasing age or impaired health have found it necessary to relinquish active official duties.

Medical Patents

The Board of Trustees finds that medical patents are now held and administered by universities, special committees and foundations and by individual physicians, that patents held under such conditions may sometimes be used to influence the progress and direction of medical research, that the Principles of Medical Ethics of the American Medical Association prevent any individual physician from deriving any income from medical discoveries, whereas technicians or laymen associated with the same discovery may profit directly, and that there is need for some standardizing or coordinating agency in this field.

The Board of Trustees therefore recommends that the American Medical Association develop as complete a list as possible of medical patents and the holders thereof, and that these holders be invited to send representatives to a national conference to be held in the headquarters of the American Medical Association for discussion of this topic, with a view to deriving therefrom recommendations leading toward suitable practice in the administration and control of medical patents.

Proposed Change in Name of Bureau of Health and Public Instruction

The Board of Trustees recommends that the name of the Bureau of Health and Public Instruction be changed to "Bureau of Health Education." The present name of the Bureau is unnecessarily long, and it is believed that the shorter name suggested by the Board of Trustees fully comprehends the Bureau's functions.

In order that the proposed change may be properly effected, it will be necessary that section 2 of chapter VI of the By-Laws of the Association be amended.

The Division of Drugs, Foods and Physical Therapy

The administrative Division of Drugs, Foods and Physical Therapy consists of the Council on Pharmacy and Chemistry, the Council on Foods, the Council on Physical Therapy and the A. M. A. Chemical Laboratory. In addition the administrative work of the Advisory Committee on Advertising of Cosmetics and Soaps is carried on in this division. A number of complex problems covering overlapping fields of the three councils have been considered by the Cooperative Committee on Policy, Rules and Procedure, representing all the groups of the division. This committee has expedited the handling of many questions and has removed the necessity of placing on a single council the burden of responsibility for interlocking questions. The creation of the division of Drugs, Foods and Physical Therapy has resulted in greater efficiency in carrying on routine activities, in obviating inconsistencies and in better correlation.

Council on Pharmacy and Chemistry

Each year the Council on Pharmacy and Chemistry has reported increasing interest on the part of the medical profession and increasing work on its own part. In 1937 a new high peak was reached in both particulars. The report of the Council's investigation of catgut sutures attracted widespread attention and apparently was instrumental in bringing about the introduction in Congress of a bill providing that the National Institute of Health formerly the Hygienic Laboratory should undertake the control and regulation of catgut sutures to insure sterility and high quality of such material. The Chair of

Sulfanilamide-Massengill episode, discussed elsewhere under the heading of the A M A Chemical Laboratory, also had great effect in causing greater interest in the Council's activities and in increasing its work. The reports on both the catgut sutures and the Elvair of Sulfanilamide incident have quickened the profession into a greater alertness to the possible dangers in the use of drug products that have been placed on the market without proper scientific investigation and without the establishment of necessary standards. So many communications have been received from physicians inquiring whether or not certain products were Council accepted or whether certain firms cooperated with the Council that it has not been possible to make prompt replies. Many institutions and individual physicians have removed from their shelves nonaccepted products. In the last three months of 1937 more approaches were made by firms with a view of obtaining Council acceptance than at any other like period. There is no doubt that more producers will endeavor to comply with the rules of the Council, in view of the increased support of the Council's work by physicians. It must be fully recognized that there are some manufacturers of products offered for therapeutic purposes that do not deserve the support of the profession. Whether or not such houses can exist under the increasingly intensive scrutiny of the medical profession waits to be seen. Certain it is that, as long as some physicians will support the crude type of products, the proprietary propaganda and the endeavor to foist commercial domination of therapeutics on the medical profession, just so long will these houses endeavor to avoid marketing their products honestly. It is gratifying, however, to note the number of new products or brands which have been submitted to the Council. One firm alone has signified its intention of submitting ninety-two products—practically all of an acceptable character—for consideration by the Council within the next few months. The difficult problem at present is how the executive force at headquarters can take care of increasing demands on the Council, not only in passing on drugs but in requests for advice and information from the physicians in active practice.

Representatives of a few firms whose method of doing business cannot receive recognition by the Council have in some instances made untrue representations that every doctor should challenge. These statements are to the effect that the Council charges a fee for examining drugs or that it 'costs too much' to get a product passed by the Council or that it is necessary to take out so much advertising in *THE JOURNAL* before the Council will accept a product. Of course such statements are completely false. It has been reiterated again and again that since its inception the Council has never accepted, or permitted to be accepted, a cent of remuneration in any form for the consideration of products. The cost of the Council on Pharmacy and Chemistry, as well as that of the other councils, is borne entirely by appropriation made by the Board of Trustees of the American Medical Association. The Council is not influenced in the slightest by any proffer of advertising patronage and, if it knows of such a proffer, the firm is notified that it will have no effect on the Council's consideration. All members of the Council, with the exception of the Secretary, serve without remuneration. They give of their time willingly and unstintingly. As an expression of appreciation of their efforts, it is asked that the profession evaluate critically the Council's conclusions and lend support to its work in rationalizing therapeutics. If any unfair charges against the Council reach the ears of members of the profession they should demand immediately that such charges be either substantiated or retracted.

PUBLICATIONS OF THE COUNCIL

New and Nonofficial Remedies—The 1937 edition differed from previous editions because of the request of some manufacturers to have official products which have been granted the seal of acceptance listed on the same pages with proprietary accepted brands. Heretofore accepted brands of official products were merely listed in that department of New and Nonofficial Remedies entitled 'List of Articles and Brands Accepted by the Council but Not Described'. Two supplements to New and Nonofficial Remedies were issued as usual, one on August 1 and one on November 1, and sent to all who had purchased copies of the book. Frequently it is noted

that physicians do not order the book annually but fall back on an old edition. This may lead to errors, because a product which stood accepted in 1930 may have been superseded by more valuable products developed since that date, further evidence might have indicated that claims made for a product should be restricted or that the tests and standards should be modified. New and Nonofficial Remedies is a current publication, the content of which is being constantly changed to keep in step with the rapid advancement of drug therapy. The number of copies of New and Nonofficial Remedies in 1937 was 5,903. The number should be much greater. In addition, 6,200 paper-bound copies were distributed, copies being sent to one class in each recognized medical school.

Epitome of the U S Pharmacopeia and National Formulary—The new Epitome was printed early in 1936. However the Pharmacopeia and the National Formulary adopted a policy of issuing interim supplements and that made it necessary to revise the Epitome in 1937. The demand for the book has been such that further printings must be made in 1938. The number of copies sold in 1937 totaled 8,130.

Useful Drugs—This little book containing a selected list of drugs has always enjoyed wide acceptance. One reason for this is that it is used in many medical schools, the other is that the book is never out of date. Early in 1937 a thorough revision was made of the 1936 edition. At the close of 1937 the manuscript had almost been completed for an entirely new edition, which will be off the press in the spring of 1938. This is the first edition of Useful Drugs in which the English name precedes the Latin name of the drug. The book is issued both in the regular pocket size and in an interleaved edition to meet the demand of teachers who desire their students to make notes alongside the text. The book not only is of service to teachers and students but is widely used as a reference guide by practicing physicians. The number of copies of Useful Drugs sold in 1937 was 6,495.

Glandular Physiology and Therapy—The book Glandular Physiology and Therapy was issued at the close of 1933. Although there has not been opportunity for the book to be revised since then, the sale still continues, 2,065 copies were purchased in 1937.

A M A Interns' Manual—This book will be a radical revision of the publication previously known as Hospital Practice for Interns. Much has been done on the text throughout the year 1937 and the manuscript was sent to the printer the first part of January 1938. It is believed that the book will receive wide recognition not only by interns but by physicians in general. It will contain official statements from the Council on Medical Education and Hospitals concerning rules for interns, an epitomized statement concerning physical therapy issued by the Council on Physical Therapy, a discussion of foods and nutrition as applied to the care of the sick, issued under the auspices of the Council on Foods, and a description of acceptable types of drugs, their dosages and indications which come within the purview of the Council on Pharmacy and Chemistry. In addition, the Council has authorized the inclusion of tables and other data that may be of aid in diagnosis.

REPORTS OF THE COUNCIL

The Council has continued to advise the medical profession concerning the status of new drugs and an increasing number of reports are appearing each year discussing the status of various substances.

A filtrate used in the treatment of gonorrhea having been the subject of two preliminary reports, was finally declared by the Council unacceptable, for lack of convincing evidence of its therapeutic value.

Soluble barbiturates for basal anesthesia received special consideration in the report on Liquid Soluble.

A report which has received wide recognition both in America and in Europe was that on 'Histidine Hydrochloride in Diet and Alkalis in Treatment of Peptic Ulcer'.

Probably no product received more attention throughout the year than did sulfanilamide on which the Council issued a number of reports and published the standards. Up to January 1, 1938 nine brands of sulfanilamide had been accepted by the Council all conforming to the rigid standards required.

A report on the standardization of digitalis products accepted for N N R and the report on dosage of preparations containing vitamins A and D have been of aid both to manufacturers and to prescribing physicians.

For a number of years the Council has insisted on limitation of the claims for the therapeutic value of Aminophylline. In its report in 1937 the Council declared that in view of accumulated evidence it could no longer recognize claims for Aminophylline for the relief of pain in angina pectoris, that claims could be made only for its use as a mild myocardial stimulant and as a diuretic.

Certain manufacturers were placing high potency vitamin D preparations on the market, particularly recommending their use in the treatment of arthritis. The Council rejected these products and pointed out the lack of any worthwhile evidence to support the claims.

The Council also ruled out the use of hydroquinone as a stabilizing agent in acceptable liver oil preparations containing vitamin A.

The Council declared unacceptable an oral vaccine for the treatment of colds.

The proprietary product "Edwenil" has been promoted to the medical profession with highly bombastic claims. An investigation undertaken under the auspices of the Council brought to light statements made by the manufacturer believed to be entirely unwarranted.

For years Avertin has been before the Council. A preliminary report was issued by the Council in 1930. After much consideration by the Council and the manufacturer an agreement was made that the other active ingredient in the product, known as Avertin Fluid, would be declared in the name and that thereafter the product would be known as Avertin with Amylene Hydrate. The product was therefore standardized, the claims were restricted, and Avertin with Amylene Hydrate is now described in New and Nonofficial Remedies.

Early in the year the Council made a preliminary report on mandelic acid and at a later date, after further confirmatory evidence had been received, accepted the product.

One of the drugs of lively current interest is Benzedrine Sulfate. An extensive report was published by the Council on the status of this product for which there has been great demand.

The foregoing is a brief summary of just a few of the numerous reports published.

The Council found it necessary to coin a number of non-proprietary names throughout the year, such as Sulfanilamide for para amino benzene-sulfonamide introduced in this country under the proprietary name of Prontylin, Riboflavin for the product previously known as vitamin B and Thiamin Chloride for the crystalline substance representing the hydrochloride of vitamin B₁.

In cooperation with the Council on Foods, the Council on Pharmacy and Chemistry has kept in close touch with the vitamin situation. During 1937 a large number of authorities in the field were selected to write articles dealing with vitamins for the purpose of publication in THE JOURNAL. With a few exceptions these articles were all in type by the first of the year and, by the time this report appears in print, the series will be well under way. The plan is similar to that used for the articles on glandular therapy. After the vitamin articles have been published, the authors will be asked to recedit them for issuance in book form. The conceptions of vitamins are changing rapidly, giving rise to unavoidable confusion. These articles should do much to clear up the confused state so far as the application of drugs to problems of therapy is concerned and will constitute a most valuable source of authoritative information. The articles are being edited under the supervision of Dr. F. C. Bang, Secretary of the Council on Foods.

In this connection it may be pointed out that pure chemical substances are taking the place of indefinite mixtures. For instance, the Council on Pharmacy and Chemistry has accepted such pure substances as Carotene which is a precursor of vitamin A, Cevitamic Acid which is a crystalline vitamin C, Thiamin Chloride which is a crystalline form of vitamin B₁, Riboflavin the pure substance previously known as vitamin B₂, and it has under consideration Nicotinic Acid and Nicotinic

Acid Amide, which are parts of the vitamin B complex. Standards have also been drawn up by the A. M. A. Chemical Laboratory for one of the crystalline vitamin D substances. A number of years ago the Council stated that the polypharmaceutical vitamin mixtures are unscientific and that there is no more reason for combining all the vitamins in a shotgun mixture simply because of their names than there is for combining all the other forty or so essential dietary ingredients. The fact that pure crystalline substances are now being made available indicates anew the value of treating disease conditions with definite substances which may be given in carefully controlled doses. The history of the vitamins and the discovery of the pure substances is not much different from the history and isolation of active principles from alkaloidal-containing plant extracts. The promulgation of unessential products under catchy names indicating their alphabetical vitamin content or the presence of so-called synergistic actions or "plus vitamin" effect is an insult to the intelligence of American physicians.

PROBLEMS BEFORE THE COUNCIL

The problems before the Council are so difficult, require so much background of experience and are so numerous that they cannot be adequately discussed in the brief space of a report. Nomenclature still looms large. The problem of nomenclature may require most extended study in the near future in view of the recent court decision involving the wax paper or "cellophane" decision. If the decisions which have now been made are upheld in the Supreme Court, the extensive manner in which proprietary names are now used will require much consideration.

The acceptance of endocrine principles has occupied a large portion of the Council's time and a number of products, such as Theelin, also known as Estrone, Theclol—also known as Estriol, Profolol Benzoate, and several other substances—are under consideration.

MEMBERSHIP OF THE COUNCIL

The Council lost none of its active members during 1937 either by resignation or by death. It did, however, suffer the loss of two former members of the Council who had much influence in its formation. Dr. Julius Stieglitz, former vice chairman of the Council and chairman of its Committee on Rules and Procedure from the inception of the Council in 1905 to the time of his resignation in 1924, died Jan. 10, 1937. It need only be mentioned that the rules of the Council today remain much the same as those formulated under the direction of Dr. Stieglitz during the early history of the Council. Dr. Stieglitz was a forceful member, recognized as a foremost authority in chemistry. After his resignation in 1924 Dr. Stieglitz maintained an active interest in the work of the Council.

Dr. George H. Simmons, Editor Emeritus of THE JOURNAL, was chairman of the Council from the time of its inception until March 1927. He continued as an active member of the Council and in February 1935 was appointed an honorary life member, in which capacity he served until his death on Sept. 1, 1937. The Council on Pharmacy and Chemistry was formed at the instigation of Dr. Simmons. Through his far-sightedness, his militant editorship and his encouragement of absolute scientific integrity, the Council was able to carry on during the early years when it encountered much opposition. Today the record of the Council on Pharmacy and Chemistry as well as that of other departments of organized medicine stands as a monument to Dr. Simmons. Even to the time of his death Dr. Simmons received the weekly transactions of the Council and took part in discussions in which he was interested. His advice, wise counsel and camaraderie are greatly missed by his former colleagues. As stated in the published resolutions of the Council: "In his death the Council has lost a member of unique value, the medical profession a servant who served it faithfully."

The following members of the Council were reelected in 1937 to serve a five year period: Dr. E. M. K. Geiling, Dr. W. W. Palmer and Dr. S. W. Clausen.

Summary

Through the creation of a Division of Drugs, Foods and Physical Therapy composed of the Council on Pharmacy and Chemistry, the Council on Foods and the

Council on Physical Therapy, it has been possible to effect closer correlation of the work of these three councils and to enhance administrative efficiency.

The work of the Council on Pharmacy and Chemistry has been greatly increased during the last year, partly because of the submission of a large number of products by manufacturers who have not heretofore cooperated with the Council and because of the nature of investigations to be made, and for the further reason that the activities of the Council are apparently being more fully supported by the medical profession generally.

The publications of the Council have been kept up to date as fully as possible and have been changed in form and scope in such manner as has been necessary to keep them abreast of scientific advancement. An important series of articles dealing with vitamins, prepared by highly qualified investigators, are being published under the auspices of the Council, and these articles will later appear in book form.

The endocrine principles and new therapeutic substances of various kinds have required prolonged and intensive consideration. Many problems requiring the attention of the Council are of more complex nature than heretofore because of refinement of chemical processes, improvement in the thoroughness of clinical and laboratory investigations, the tendency toward specificity, the necessity for establishing standards and other factors of major importance.

There are still some manufacturers of products offered for therapeutic use who do not employ the necessary methods of investigation and check to insure either the purity or the usefulness of their products, but the continued use of such products cannot be sustained except as they are employed as therapeutic agents by members of the medical profession in their daily practice. The efforts of the Council on Pharmacy and Chemistry to establish rationalism in therapeutics deserve and should have the fullest support from all members of the medical profession.

Through the Committee on Therapeutic Research of the Council on Pharmacy and Chemistry, grants have been made for the support of scientific investigations conducted by qualified investigators whose projects have been approved by the committee and some very valuable reports have been published.

Council on Physical Therapy

Among the noteworthy accomplishments of the Council on Physical Therapy during the past year have been the establishment of standards for acceptable audiometers, the investigation of hearing aids, the examination of short wave diathermy apparatus, the advancement of the Council's educational activities and a wider distribution of information on physical therapy. As usual, a large part of the time of the Council has been devoted to advising the profession about the status of apparatus

EDUCATIONAL ACTIVITIES

Gratifying results of the educational program under the direction of the Council are shown by the increased number of inquiries concerning graduate courses in physical therapy and teaching outlines for such courses from deans of medical schools. Requests for aid in planning physical therapy departments continued requests for instructional films and inquiries concerning accepted and rejected apparatus have been given careful attention. The Council on Medical Education and Hospitals has lent encouragement to this educational program.

It has been the aim of the Editorial Committee and the Committee on Education of the Council to acquaint the rank and file of the medical profession with the value of physical therapy, particularly of simple measures heat light and massage. This has been done largely by the publication of articles by lectures and by exhibits in addition to other educational activities. Besides reports concerning acceptable and non-acceptable apparatus other reports have appeared in THE JOURNAL setting standards for certain physical therapy equip-

ment, such as "Minimum Requirements for Acceptable Audiometers," "Evidence Required by the Council on Physical Therapy for Consideration of Apparatus Used in Fever Therapy," "Status of Diathermy and Short Wave Diathermy," "Physical Therapy in Hospitals With Fifty or More Beds," "Adopted articles have appeared in THE JOURNAL on Physical Therapy in Infantile Paralysis" and "The Present Status of Short Wave Diathermy." A section on "Physical Therapeutics" has been prepared and is being included in the next edition of the Handbook for Interns. The supply of the second edition of the Handbook on Physical Therapy has been exhausted and a revision is scheduled. The booklet "Apparatus Accepted" is to be revised and made much larger.

Other educational activities of the Council include work with state and county medical societies, such as arrangement of programs, presentation of papers stressing the value of physical therapeutic measures, planning exhibits and lending films. Outworn films will be replaced as soon as possible. During the year the Council sponsored six exhibits in cooperation with the Committee on Scientific Exhibit of the American Medical Association, including one at Atlantic City. In this exhibit a series of lectures was given on the fundamental physical principles employed in electrical apparatus used for therapeutic purposes, short lectures were given on the use of physical agents, and a report of research was sponsored by the Council.

Because of an increased demand for instructional material a suggested outline of lectures on physical therapy has been prepared and made available to deans of medical schools. Progress in this field is noted by the establishment of several graduate courses in physical therapy with fellowships.

INVESTIGATION OF APPARATUS

Evidence of the closer cooperation between manufacturers and the Council is indicated by the withdrawal from the market of certain devices that have been declared nonacceptable although in many cases the reports were not published. In some instances new units have been designed to meet Council requirements, and in others existing devices have been changed to conform with suggestions of the Council. Manufacturers are being impressed with the necessity of presenting advertising copy to the Council for criticism and suggestions prior to publication of the report thus eliminating many misleading advertising claims and bringing about better standards in physical therapy. The submission of a wider range of therapeutic and diagnostic equipment shows the growing importance placed on the Council's seal of acceptance.

More short wave diathermy units have been considered than any other type of equipment with ultraviolet radiation device next in number. Other types of products considered are air filters, anesthetic apparatus, audiometers, hearing aids, bird cages, fever cabinets, sterilizing outfits, insufflators and a variety of equipment for oxygen therapy including regulator, rebreathing outfits, nasal catheters, face tents and humidifiers. Owing to the number of devices considered, there is an ever increasing volume of correspondence passing through the secretary's office.

SPECIAL INVESTIGATIONS

Audiometers—A joint meeting of manufacturers of audiometers and hearing aids and a group of otologists appointed by the Council was held, at which many interrelated problems were discussed and agreements reached that aided in the formulation of regulations for acceptable audiometers. The expert advice given by the consultants contributed much in paving the way toward standardization of these instruments. Although this work is not completed the progress made thus far indicates that these studies will be of great benefit to many thousands of persons with defective hearing. Tentative Minimum Requirements for Acceptable Audiometers were published in THE JOURNAL. The National Bureau of Standards, the American Society for the Hard of Hearing and the American Standards Association have rendered the Council valuable assistance in considering audiometers and hearing aids.

Research—Five grants were awarded to aid in research during the past year. These grants are available to competent investigators who make application and who in the opinion of

the Committee on Scientific Research of the Council on Physical Therapy, have problems of merit. Six articles were published by the recipients during the past year, reporting on research made possible by these grants.

Radiation—There is not at present sufficient critical evidence available to substantiate the value of radiation from the mercury glow lamp in the prevention and cure of rickets in children nor are there critical data to support the claims made for bactericidal action of ultraviolet radiation *in vivo*, although evidence shows that cultures of bacteria may be made sterile by ultraviolet irradiation in Petri dishes. Consequently the Council is giving careful consideration to both problems. An attempt might well be made to establish standards of equivalents for chemical substances and radiant energy, particularly ultraviolet.

The investigation of radium and radon seeds has progressed satisfactorily. It is expected that reports will be made available to the profession during the coming year.

Although no reports have been published, the Council is going forward with the consideration of x-ray equipment.

Ophthalmic Devices—Consultants on ophthalmology, appointed by the Council, have given consideration to ophthalmic equipment for which therapeutic and diagnostic claims are made. The consultants have rendered valuable service and undesirable instruments and equipment have been withdrawn from the market as a result of their efforts.

Fever Therapy Apparatus—A Committee on Hyperpyrexia, appointed by the Council, formulated certain requirements in relation to fever therapy equipment and its conclusions were published in *THE JOURNAL* under the heading "Evidence Required by the Council on Physical Therapy for Consideration of Apparatus Used in Fever Therapy."

Summary

The principal achievements of the Council on Physical Therapy during the past year have been the establishment of standards for acceptable audiometers, the investigation of hearing aids, the examination of short wave diathermy apparatus and the advancement of the Council's educational activities with a wider distribution of information on physical therapy.

Under the auspices of the Council, a joint meeting of representatives of manufacturers of audiometers and hearing aids with Council appointed consultants paved the way for a more prompt agreement on standards for acceptable audiometers and facilitated better understanding of interrelated problems. The cooperation secured from the manufacturers of these devices is most gratifying to the Council.

Beneficial results of the educational program launched several years ago are now being noted, though much remains to be done.

As usual the Council has continued with its investigation of and reporting on apparatus submitted for the purpose, and in some instances it has investigated and reported on products not presented. The consideration of short wave diathermy apparatus has predominated in the Council's investigating activities.

Research grants awarded to investigators presenting problems of merit have reaped gratifying results and several excellent articles have been published.

Council on Foods

During 1937 the efforts of the Council on Foods to promote truthful advertising of wholesome food products continued unabated. It is gratifying to report that many producers have continued to accord the Council their full cooperation in this work. Much of this labor may go unrecognized because it consists of the elimination of misleading health claims before they appear in advertising directed both to the medical profession and to the public. The importance of the constant efforts of the Council in this connection scarcely can be evaluated but review of advertising is only one phase of the Council's activities.

The demands made on the Council's facilities are increasing constantly and, of course, the demands on the time of the individual members of the Council are increasing likewise. Matters given consideration during the year have included such diverse questions as the claims made for "one formula preparations" used in feeding infants, the nutritional value of the proteins of milk, the dietary significance of fruit juices, and many others which have been reported from time to time in *THE JOURNAL*. The problem of lead in foods received particular attention, and from a review of the evidence obtainable it was concluded that the products standing accepted by the Council contain either no lead or minute traces which are of no known hygienic significance. This question is important and is being investigated further. Another topic considered was the difficult question of how foods can be rated as sources of the dietary essentials. A suggested procedure for judging the value of foods as excellent, good or fair sources of the different dietary factors has been published.

REPORTS OF THE COUNCIL

The Council has been in a unique position with regard to having information on the commercial preparation of many food products. This information has been utilized along with other facilities of the Council, in the preparation of informative reviews on the nutritional value of foods and interpretations of evidence available in the literature with regard to nutritional problems. General reports have been published on a number of subjects and a brief review of some of them follows.

The theory has been advanced in some quarters that cereal products contain a toxic decalcifying substance and, in order to overcome the effects of this hypothetical factor, it would be well to fortify cereals with a calcifying substance such as vitamin D. After reviewing available evidence, the Council concluded that there is no good evidence for the existence of this hypothetical toxin. Hence there appears to be no necessity at the present time to fortify cereal products intended for general human consumption with vitamin D in order to overcome the effects of an alleged toxic factor.

Dextrose is the normal sugar of the blood and studies of its physiologic importance have been made since the days of Claude Bernard. Recent commercial developments have led to the production and marketing of pure dextrose at a comparatively low price. This sugar, therefore, has become widely used both as a food itself and as an ingredient of manufactured food products. Comparative claims have led the Council to review and to evaluate the available evidence on the place of dextrose in the diet of normal persons. It is considered that dextrose is well utilized as a food but that it possesses no practical advantages over many other carbohydrates in combating ketosis produced by either a ketogenic diet or in early stages of fasting. Contrary to some claims, dextrose itself does not have unique advantages when administered by mouth in the prevention or relief of fatigue or in the maintenance of muscular efficiency. Considerations of allowable claims for dextrose appear in the full report.

Another report summarized available information on the production and properties of milks which produce a soft curd. An attempt was made to evaluate the nutritional significance of these milks, particularly in the feeding of infants. The Council concluded that pasteurization has little effect on the nature of the curd but that softening of the curd may be accomplished by boiling, dilution, addition of acids or alkalis, addition of various cereal waters, removal of some of the ionizable calcium, homogenization, evaporation or drying, and that in general, digestion in the stomach of milk with a low curd tension is more rapid than the digestion of milk which does not have this property.

Strained fruits and vegetables are useful for infant feeding because of their physical texture, nutritive properties and their psychologic value in teaching the infant at an early age to receive food from the spoon and to accept a variety of flavors and textures. Strained foods usually may be fed between the fourth and the sixth month though this is a question for the physician to decide as is the matter of replacing such products with coarser foods. In this report the Council also states that home strained foods properly prepared are fully as nutritious as commercial products.

Another report of the Council provides a brief survey of available evidence relative to the usefulness of fresh apples and preparations of dried and powdered apples in the dietary treatment of diarrhea in infants and small children. There is evidence that the apple is effective in the treatment of such conditions, though the mechanism responsible for the reported success is not clear. The Council emphasizes that the use of the apple or preparations of the apple does not preclude the necessity of other measures such as parenteral administration of fluids when indicated, the careful selection of a suitable transition diet, and competent pediatric supervision.

There has been considerable discussion of the merit of spinach as a food. In a review of published reports from scientific and medical literature, the Council concluded that spinach should be regarded as a wholesome and valuable food. Spinach is a rich source of vitamin A and contributes vitamin C, iron and roughage to the diet. The evidence shows that the iron of spinach is not wholly available, nor is it a good source for infants in amounts which they can digest. The calcium is not utilized because it is present largely in the form of insoluble calcium oxalate.

GENERAL DECISIONS

In its report on vitamin D milk, the Council stated, "For the present milk is the only common food which will be considered for acceptance when fortified with vitamin D." This decision now has been amended by the Council so that milk products which are used in the same manner and for the same general purposes are included under the term "milk." This means that not only fluid milk but evaporated milk, dried milk, dried skimmed milk and flavored milk drinks prepared from whole or skimmed milk (provided the volume of milk in the prepared drink is at least 80 per cent of the total volume) will be eligible for acceptance when fortified with vitamin D.

The Council has been insisting that its seal does not constitute recommendation of any food product. Manufacturers of some accepted products have been using a statement on their labels such as "Recommended as a carbohydrate supplement to milk in infant feeding." The Council considered that this statement constitutes an infraction of its rules particularly when the phrase "recommended for" appears in close association with the seal of the Council. Firms have been informed that substitute phrases such as "suitable for," "useful for" or "adapted to" might be used in place of the phrase "recommended for."

GENERAL POLICIES

Two years ago it was decided that the facilities of the Council should be conserved by acceptance of only those food products which seem to require attention. In 1936, carbonated beverages and the syrup bases from which some of them are made, breads and other ordinary bakery products were included in the "exempted list" because it was believed that there was no longer a need to act on them. During the past year, "exemption" without prejudice to the products themselves has been extended to cover a number of other food products. Foods falling in the foregoing category and having nutritional value beyond that of ordinary products, or which are promulgated with special claims, will be considered and reported on by the Council when such action is considered desirable. Manufacturers that have cooperated with the Council are being given every possible consideration in the matter of disposal of labels and advertising bearing the seal of acceptance.

MEMBERSHIP AND CONSULTANTS

During the year the terms of membership of Dr. Mary Swartz Rose and of Dr. Philip C. Jeans expired and they were reelected by the Board of Trustees to serve another period of five years.

Among the persons called on as consultants during the year, the services of the following are gratefully acknowledged: Dr. Henry C. Eckstein, Dr. H. J. Fisher, Miss Mary A. Foley, Dr. Ramon F. Hinzal, Dr. Elmer N. Nelson, Dr. Genevieve Stearns, Dr. William C. Rose, Dr. Grace MacLeod, Dr. Margaret Hessler Brookes, Miss Ruth Blair, Dr. Evelyn G. Halliday and Dr. Henry C. Sherman.

Summary

The efforts of the Council on Foods to promote truthful advertising of wholesome food products and to develop scientific progress in the field of nutrition have been carried on intensively. There is a constantly increasing demand on the services of the Council and an earnest effort has been made to meet the demand as fully as possible.

The Council has given careful and thorough consideration to a large number of important problems, some of which have lately developed, and has published numerous reports dealing with matters of varying nature that have demanded official attention. It has been necessary in order to conserve the facilities of the Council to exempt many products that were formerly considered.

The Council on Foods has had the benefit of the services of a number of distinguished scientists, who have cooperated in the study of numerous scientific questions and who have given able assistance in conducting necessary scientific investigations.

The Chemical Laboratory

An achievement of the A. M. A. Chemical Laboratory in 1937 was the investigation of Elixir of Sulfanilamide, Massengill. While the work was done under the auspices of the Laboratory, the facilities of the Council on Pharmacy and Chemistry were utilized, and, since the Laboratory is a unit of the headquarters' administrative Division of Drugs, Foods and Physical Therapy, there was close cooperation between them. Although the story of the Elixir of Sulfanilamide incident is well known by this time, certain observations are in order. The Laboratory determined the composition of the Elixir of Sulfanilamide, it analyzed specimens which had been used by patients who had died, specimens obtained on the open market and the contents of a gallon bottle ordered directly from the manufacturer. As soon as the composition was determined, "synthetic" and "modified synthetic" mixtures were prepared. These were then turned over to Dr. E. M. A. Geiling and his collaborators of the Department of Pharmacology of the University of Chicago, who tested them along with sulfanilamide alone and with the Elixir itself. Experimental animals had the same symptoms and died within approximately the same time as the patients, whether given the 'Elixir of Sulfanilamide' or the solution containing the diethylene glycol in similar amounts. Necropsies were reported by Dr. Paul R. Cannon of the Department of Pathology of the University of Chicago on animals which had been so killed and these in turn were compared with sections of kidneys and livers from patients who had succumbed. There was close cooperation with the Food and Drug Administration of the federal government, which did excellent work in tracing all shipments which had been placed on the market. As soon as the government inspectors reported deaths, the headquarters office of the American Medical Association was notified and contact was immediately established by telephone or telegram with the physicians concerned. Seventy-six deaths were confirmed in this manner. In addition, fifteen or twenty deaths of patients who took the Elixir were reported but it was definitely established that this drug was exclusively responsible or, in some cases, confirmatory evidence could not be obtained.

Within a week after the first report of poisonings was received, the Laboratory had completed analytic tests and Dr. Geiling and his co-workers had made sufficient tests on animals to show that diethylene glycol was toxic in the amounts given. As soon as the essential facts were established public announcement was made through the lay press as well as through scientific publications. The entire problem was solved in less than two weeks after the first sample of the product at fault was received by the Laboratory. This illustrates anew the value of the organization maintained by the Association, including trained chemists who may be asked to emergency problems immediately, splendidly qualified advisers, who put aside everything to push through this policy of militant editorship and an organized method of

out news, the Board of Trustees, which provides funds and equipment to make possible prompt and effective action in dealing with emergencies. The reports were made available to the medical profession in record-making time. This situation, tragic as it was, has served as an excellent opportunity of bringing home to Congress and to the public the necessity for an effective food and drug act. Already, legislation has been introduced in both houses of Congress to forestall similar tragedies. Appreciative acknowledgment is made to the Tulsa group of physicians who first brought the matter to the attention of the Laboratory and whose report on clinical and pathologic observations aided the work in Chicago. Acknowledgment is also made to other physicians in various places. Dr O E Hagebusch of St Louis contributed a fine pathologic report. Dr Geiling with his associate, Julius M. Coon, and Dr Paul R. Cannon gave unstintingly of their time while investigations were under way. Thanks are also due to their colleagues in the biologic science group of the University of Chicago. Dr E K Marshall Jr and Dr J Howard Brown of Johns Hopkins University aided in the problem. Special recognition is due Mr W G Campbell and Mr J O Clarke of the Food and Drug Administration, who directed the splendid work done by that agency. The members of the A M A Chemical Laboratory staff who worked on this problem were Dr E W Schoeffel, Dr H R Kreider and Dr J B Peterson. Dr Schoeffel deserves special mention because of the prodigious amount of work he did with a minimum amount of rest. The Board of Trustees at its November meeting expressed its appreciation by a formal vote of thanks.

GENERAL ACTIVITIES

The work of the Laboratory during the year included establishing standards, among other products, for Cobefrin Hydrochloride, Novatropine, Propadrine Hydrochloride Effervescent Calcium Gluconate, Benzadrine Sulfate Sulfanilamide, Riboflavin, Thiamin Chloride (Vitamin B₁ Hydrochloride), Gitalin, several endocrine principles which were standardized for the first time, Avertin with Amylene Hydrate, Mecholyl, Silver Picrate, and bismuth preparations. The Laboratory has also analyzed several products which were the subject of reports by the Bureau of Investigation and has carried out a mass of routine work.

Members of the Laboratory staff appeared before scientific societies, either discussing work done by the A M A Chemical Laboratory or giving lectures of a popular character. Papers are in preparation or have been submitted to journals dealing with the comparative analysis of crystalline preparations containing insulin—probably insulin zinc. Another paper deals with the standardization of Thiamin Chloride, wherein the chemical method is described as a substitute for the old method of biologic assay while another deals with the chemical determination of glycol and glycol ethers. A paper describing the A M A Chemical Laboratory, particularly its microscopic and spectroscopic facilities, has been published in the analytic edition of *Industrial and Engineering Chemistry*. A motion picture prepared by A M A chemists, illustrating certain microchemical technique and the use of other laboratory apparatus, has been used by a number of societies in order to follow this work.

The laboratory has also prepared book reviews answered inquiries and cooperated with *THE JOURNAL* and other departments of the Association.

Summary

An important accomplishment of the Chemical Laboratory in the past year resulted from investigations of the poisonous effects of a product known as Elixir of Sulfanilamide. These investigations were made with the aid of the Council on Pharmacy and Chemistry, of members of the scientific staff of the University of Chicago, of members of the Food and Drug Administration of the Department of Agriculture of the federal government, and of individual physicians. It was clearly established that at least seventy-six deaths were due to the use of this product and that the toxic agent involved was diethylene glycol.

Much work was done by the Laboratory during the year in establishing standards for important therapeutic

products. The usual laboratory investigations of products submitted by the Council on Pharmacy and Chemistry and those submitted by the Bureau of Investigation were conducted. Members of the Laboratory staff have contributed to the programs of several important scientific societies during the year, and papers presented have been published. Members of the staff have also participated in educational programs before public audiences. A motion picture pertaining to the work of the laboratory has been shown before a number of scientific groups.

Council on Industrial Health

In accordance with instructions received from the House of Delegates at the Atlantic City session in 1937, the Board of Trustees has established a Council on Industrial Health with the following official personnel: Dr Stanley J. Seeger, Chairman, Milwaukee; Dr Harvey Bartle, Philadelphia; Dr L D Bristol, New York; Dr Warren F. Draper, Washington, D C; Dr Leroy U. Gardner, Saranac Lake, N Y; Dr Morton R. Gibbons, San Francisco; Dr H H. Kessler, Newark, N J; Dr A J. Lanza, New York; Dr A D. Lazenby, Baltimore; Dr Earl D. Osborne, Buffalo; Dr C W. Roberts, Atlanta, Ga; Dr C D. Selby, Detroit; and Dr Carl M. Peterson, Secretary, Chicago.

The Board of Trustees had recognized the need for establishing measures whereby the American Medical Association might be in position to aid in the solution of important problems that have arisen in the field of industrial health. The Section on Dermatology and Syphilology had interested itself intensively in the study of industrial dermatoses and had adopted a report of a special committee of the section asking for the cooperation of the Association in the establishment of a clearing house for the accumulation and recording of information on industrial dermatoses.

In March 1937 the Board of Trustees invited a relatively large group of physicians who were known to have had wide experience in the field of industrial health to participate in a conference at the Association's offices. The discussions at this conference, which occupied an entire day, dealt with many important problems, and it was the unanimous opinion of the consulting group that the American Medical Association should establish the Council on Industrial Health. At the Atlantic City session in June 1937 the Board of Trustees was authorized by the House of Delegates to proceed with organization of the Council as a standing committee of the Board of Trustees.

The Council on Industrial Health held its first meeting on Dec 10, 1937, at which consideration was given to the details of organization and to a discussion of the possible functions that might be assumed and of the scope of work to be undertaken. Committees were appointed to report at a later meeting of the Council, which was held in Chicago on March 26, 1938. At the second meeting, as the result of recommendations submitted by these committees, plans for the initial activities of the Council were adopted. These plans involve investigations of present activities in the field of industrial health on the part of various groups and organizations, including governmental agencies, industries, labor organizations and other interested groups.

It is the intention of the Council on Industrial Health to establish and to maintain official contact with constituent state medical associations. These associations will be requested to create committees on industrial health to cooperate with the Council in the study of problems with which that body may be properly concerned, in compiling information and in developing methods and measures that may enable the American Medical Association to make helpful contribution toward the solution of these important problems.

The Council hopes that it will be possible to arrange for an annual conference on industrial health to be held in Chicago. Committees were appointed to undertake the preparation of special articles that may be published in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*. The Council on Industrial Health will endeavor to establish close cooperative effort with the Council on Medical Education and Hospitals for the purpose

of promoting graduate facilities in the field of industrial health. One committee is engaged in the important task of studying nomenclature, and this committee will attempt to lay the ground for a standard nomenclature in the particular field with which the Council is concerned. Another important activity of the Council will be concerned with a study of those provisions of compensation laws which may have a direct bearing on industrial health.

The office of the Council on Industrial Health is located in the Association's building at 535 North Dearborn Street, Chicago, under the immediate direction of Dr. Carl M. Peterson, Secretary of the Council.

Summary

The Council on Industrial Health, organized in December 1937, has held two official meetings and has developed a working organization through the appointment of a secretary and the creation of official committees. Articles dealing with various subjects of major importance in the field of industrial medicine are in course of preparation for publication. The Council has adopted official rules and is proceeding as rapidly as possible, with due conservatism, toward the prosecution of plans that have been officially adopted.

Advisory Committee on Advertising of Cosmetics and Soaps

The Advisory Committee on Advertising of Cosmetics and Soaps was organized during the past year. It has issued only one statement but has considered quite a number of cosmetic preparations which *THE JOURNAL* has been asked to advertise in its pages. Firms have been given a liberal amount of time in which to revise advertising. The number of members on the Committee has been increased from three to five, with two ex-officio members in addition. The Committee plans to issue reports during 1938 and hopes at an early date that the preliminary work will have progressed to such an extent that reports may be made on all the cosmetic products which are submitted to *THE JOURNAL*.

Bureau of Legal Medicine and Legislation

FEDERAL LEGISLATION

Except where otherwise indicated, the following report on federal legislation speaks as of March 24, 1938. The legislation discussed includes some that was pending in the first session of the Seventy-Fifth Congress when the House of Delegates last met, some that was introduced during the special session that followed, and some introduced in the third session that convened in January and at present writing is still continuing. An effort has been made to bring the information as nearly up to date as is practicable, regardless of the calendar year covered by other portions of this report.

An analysis of the laws passed during the first and special sessions of the Congress and of the bills pending when the second regular session convened, Jan. 3, 1938, was published in the January 15 and 22 issues of *THE JOURNAL*.

Federal Health Insurance.—S. Res. 143, a resolution introduced by the former Senator Black of Alabama, would authorize the Senate Committee on Education and Labor to make a full and complete investigation in order to determine the best and most effective kind of Federal legislation to provide a national public-health policy throughout the entire United States and to report to the Senate as early as practicable the recommendations outlining the kind of legislation it is believed will most effectively accomplish this purpose. This resolution is still before the Committee on Education and Labor, to which it was referred.

S. Res. 855, introduced by Senator Capper of Kansas, is entitled "A Bill to aid in alleviating the loss caused by sickness." This bill proposes the establishment of a federal system of health insurance and is patterned after the so-called Epstein health insurance bill. It was referred to the Senate Committee on Finance. It is still before that committee.

S. J. Res. 188, introduced by Senator Lewis of Illinois, is a resolution "to provide medical aid for the needy and stricken with illness who are unable because of poverty to provide treatment and hospitalization, also to establish and license medical practitioners as civil officers of National Government." This resolution was referred to the Senate Committee on Finance, where it still is.

H. R. 8237, introduced by Representative Voorhies of California, "to provide for the general welfare by establishing a Cooperative Home Board and a system of Cooperative Home Associations," proposes that the Public Health Service will supply and supervise the medical service needed by members of the proposed associations and supervise the sanitary facilities of their homes. It was referred to the House Committee on Banking and Currency, where it still is.

H. R. 9847, introduced by Representative Treadway of Massachusetts, by request, proposes to establish a national system of health insurance. This bill was introduced as late as March 14, 1938. It was referred to the House Committee on Interstate and Foreign Commerce and is still in that committee.

H. Res. 452, submitted March 28, by Representative Scott of California, contemplates the creation of a special House committee to investigate the activities of the American Medical Association, state and county associations and the Medical Society of the District of Columbia in connection with Group Health Association, Inc., of the District of Columbia. The resolution was referred to the House Committee on Rules.

Federal Health Activities and Subsidies.—Health Activities. Generally, H. R. 4475, introduced by Representative Voorhies of California, proposes "to increase authorization of appropriations for Public Health Service under the Social Security Act." This bill would increase the appropriation for aid by the United States Public Health Service to states, counties, health districts and political subdivisions from \$8,000,000 annually to \$20,000,000 annually and to increase the appropriation for the Public Health Service annually from \$2,000,000 to \$5,000,000, for investigation of disease and problems in sanitation, in accordance with the terms of the Social Security Act.

Cancer. S. 2067, a bill entitled "A Bill authorizing the Surgeon General of the Public Health Service to control and prevent the spread of the disease of cancer," was introduced April 2, 1937, by Senator Bone of Washington, on behalf of himself and ninety-four other senators, out of a total Senate membership of ninety-six. A companion bill, H. R. 6100, was introduced in the House of Representatives by Representative Magnuson of Washington.

Another cancer bill was introduced, H. R. 6767, by Representative Maverick of Texas, a bill "to promote research in the cause, prevention and methods of diagnosis and treatment of cancer, to provide better facilities for the diagnosis and treatment of cancer, to establish a National Cancer Center in the Public Health Service and for other purposes."

H. J. Res. 428, relating to cancer, was introduced by Representative Hunter of Ohio, a joint resolution "to provide for the establishment of a National Health Center, as a permanent memorial to Thomas Jefferson, for the purpose of promoting research in the cause, prevention, and methods of diagnosis and treatment of cancer, to provide better facilities for the diagnosis and treatment of cancer, to establish a National Health Center in the Public Health Service, and for other purposes."

All these bills and the joint resolution were made the subject of a hearing before a joint meeting of a subcommittee of the Senate Committee on Commerce and a subcommittee of the House Committee on Interstate and Foreign Commerce. As a result there was evolved an Act to provide for, to establish and aid in coordinating research relating to cancer, to establish the National Cancer Institute, and for other purposes, which was approved by the President Aug. 5, 1937 and became effective thirty days later. The act is referred to as the National Cancer Institute Act. It established in the Public Health Service a division known as the National Cancer Institute, under the direction of the Surgeon General of the Public Health Service.

Health Service and a National Cancer Advisory Council appointed by him. The Council is authorized—

- (a) To conduct assist and foster researches investigations experiments and studies relating to the cause prevention and methods of diagnosis and treatment of cancer
- (b) To promote the coordination of researches conducted by the Institute and similar researches conducted by other agencies organizations and individuals
- (c) To procure, use and lend radium as hereinafter provided
- (d) To provide training and instruction in technical matters relating to the diagnosis and treatment of cancer
- (e) To provide fellowships in the Institute from funds appropriated or donated for such purpose
- (f) To secure for the Institute consultation services and advice of cancer experts from the United States and abroad and
- (g) To cooperate with State health agencies in the prevention control and eradication of cancer

The act authorized an appropriation not to exceed \$750,000 for the erection and equipment of a suitable and adequate building and facilities for the use of the institute and the appropriation annually of \$700,000 for the purpose of carrying out the provisions of the act

The establishment of the National Cancer Institute, however, did not check proposals on behalf of cancer sufferers. H R 8564, introduced by Representative Towey of New Jersey, since deceased, proposes "to establish a national foundation for the purpose of promoting research into the cause, prevention, methods of diagnosis and treatment of cancer, and for other purposes." This bill was referred to the House Committee on Interstate and Foreign Commerce, where it still is. And H J Res 468, a joint resolution to dedicate the month of April in each year to a voluntary national program for the control of cancer, was introduced by Representative Rogers of Massachusetts. This joint resolution proposes that the President shall issue annually a proclamation setting aside the month of April of each year as Cancer Control Month and shall invite annually the governors of the several states and territories and possessions of the United States to issue proclamations for like purposes. It was referred to the House Committee on the Judiciary and was reported, March 10, 1938, with a recommendation that it pass. It has passed the House and Senate.

H R 8655, introduced by Representative Dunn of Pennsylvania, proposes to provide \$200,000,000 for the prevention and cure of cancer, infantile paralysis, tuberculosis, blindness, deafness and other social diseases. It was referred to the House Committee on Interstate and Foreign Commerce, where it still is.

Veneral Diseases. H R 3680 was introduced by Representative Pfeifer of New York, to amend the Social Security Act by authorizing an appropriation of \$25,000,000 for the control of venereal diseases. This bill proposes an appropriation of \$25,000,000 annually to assist states, counties, health districts and other political subdivisions of the states in establishing and maintaining adequate services for the prevention, control and treatment of venereal diseases, the money to be distributed under the federal subsidy system and the work done to be under the supervision and control of the Surgeon General of the Public Health Service. This bill was referred to the House Committee on Ways and Means and it is still there.

H R 7850 was introduced by Representative Boren of Oklahoma to authorize an appropriation of \$4,000,000 for the control of venereal diseases, and for other purposes. This bill proposes to authorize an appropriation of \$4,000,000 to remain available until expended, to be allotted to the several states by the Surgeon General of the Public Health Service for expenditure by such states for the control of venereal diseases. This bill was referred to the House Committee on Interstate and Foreign Commerce where it still is.

H R 9047, introduced by Representative Bulwinkle of North Carolina proposes to impose additional duties upon the United States Public Health Service in connection with the investigation and control of the venereal diseases. This bill is similar to S 3290 discussed later, introduced by Senator La Follette of Wisconsin. H R 9047 proposes to authorize appropriations for federal subsidies, to be distributed by the Surgeon General of the Public Health Service among the several states apparently at his discretion, beginning at \$3,000,000 a year and

reaching in the fiscal year ending June 30, 1942, the sum of \$25,000,000, which amount, it is proposed, shall be appropriated annually. The only additional duty it proposes to impose on the Surgeon General seems to be the supervision and control of the work done by the several states on the basis of the grants of public moneys that he makes. This bill was referred to the House Committee on Interstate and Foreign Commerce, where it now is.

S 3290, Senator La Follette's bill, was referred to the Senate Committee on Commerce, which recommended its enactment after reducing the appropriations to the following amounts for the fiscal year ending June 30, 1939, \$3,000,000, for the fiscal year ending June 30, 1940, \$5,000,000, for the fiscal year ending June 30, 1941, \$7,000,000, and for each of the ten fiscal years thereafter such sum as may be needed to carry out the purposes of the act. This bill is now on the Senate Calendar.

H J Res 572, introduced by Representative Boren of Oklahoma, proposes to require a report from the Public Health Service, during the current session, which began Jan 3, 1938, of "(1) all facts pertaining to the prevention of syphilis, with particular reference to the steps which have or may be taken by such Service to assist in the prevention of such disease, and (2) any recommendations for legislation or other action by the United States which such Service may deem necessary in the prevention of such disease." This resolution was referred to the House Committee on Interstate and Foreign Commerce, where it now is.

Tuberculosis. H R 8131, introduced by Representative Terry of Arkansas, proposes to provide for tuberculosis hospitals and their operation. It proposes to authorize an appropriation of \$5,000,000 annually for five years, to enable each state to make adequate provision of hospital beds for tuberculous patients. The money is to be spent under the direction of the Surgeon General of the Public Health Service. Payments are to be made to the several states from time to time on the certificates of the Surgeon General, showing that the state to be paid "has submitted a satisfactory plan for provision of hospital care for tuberculous patients and which has appropriated from its own funds 25 per centum of the total sum required to carry out the plan." This bill was referred to the House Committee on Interstate and Foreign Commerce, where it still is. An identical bill, S 2746 was introduced in the Senate by the late Senator Robinson, July 6, 1937, and referred to the Senate Committee on Education and Labor. It is still in that Committee.

S 123, introduced by the late Senator Robinson, by request, proposes "to provide for tuberculosis hospitals and for their operation." This bill proposed to authorize an annual appropriation of \$5,000,000 for an indefinite period, "for the purpose of enabling each State to provide and operate at least one hospital bed for tubercular patients to each annual death from tuberculosis." Payments will be made, the bill proposes, to states which have submitted, and had approved by the Surgeon General of the Public Health Service state plans for such hospitalization. This bill was referred to the Senate Committee on Education and Labor, where it still is.

H R 8655, introduced by Representative Dunn of Pennsylvania, proposes to authorize the appropriation of \$200,000,000 for the prevention of certain diseases, among them tuberculosis. The other diseases covered by the appropriation are cancer, infantile paralysis, blindness, deafness and other social diseases. This bill was referred to the House Committee on Interstate and Foreign Commerce where it now is.

Infantile Paralysis, Blindness, Deafness and Other Social Diseases. H R 8655 introduced by Representative Dunn of Pennsylvania proposes to provide \$200,000,000 for the prevention and cure of cancer, infantile paralysis, tuberculosis, blindness, deafness and other social diseases. The President is to be empowered to draw from the federal treasury the amount or money specified to carry out the provisions of the act but no restrictions whatever are imposed on the methods to be used to accomplish the ends aimed at.

Silicosis and Related Dust Diseases. H R 7971 and H R 9689 both introduced by Representative O'Connell of Montana propose to regulate interstate commerce in goods produced under conditions exposing employees to the hazards of

silicosis and related dust diseases" To accomplish that end, the bills would make it unlawful for any person to ship or deliver for shipment goods in interstate or foreign commerce if they were produced in any mine, quarry, mill, workshop, factory or other place of employment situated in the United States in which silica dust or other harmful dust hazard is present, in violation of any orders prescribed by the Secretary of Labor, which orders the secretary is to be authorized by the act to issue The bills were referred to the House Committee on Labor, where they still are

Hospitals for the "Medically Needy" S 3631, introduced by Senator Pepper of Florida, is a bill to provide for assistance to states, counties, health districts and other political subdivisions of the states in the construction of additional hospital facilities for the medically needy For the construction of such hospitals, including health centers, the bill proposes annual appropriations of \$200,000,000 for five years, for the maintenance of such hospitals, annual appropriations of \$73,000,000 for five years, and to assist states, counties, health districts and other political subdivisions to provide hospital care for the "medically needy" annual appropriations of \$1,000,000 for five years The federal appropriations proposed by this bill are to be allotted by the Public Health Service to the several states on the basis of (1) the extent of need for additional hospital facilities and hospital care for the "medically needy" and (2) the financial needs of the respective states The money allotted must be spent in accordance with plans approved by the Surgeon General of the Public Health Service

Medical Care for Transients H R 9256, introduced by Representative Voorhis of California, proposes to amend the Social Security Act to provide for aid to states for the care of transients The bill proposes to authorize an appropriation of \$10,000,000 for the fiscal year ending June 30, 1938, and for each fiscal year thereafter a sufficient sum to carry out the purpose of the bill, such sums to be allotted to the several states for the purpose of enabling them to furnish financial assistance or other assistance, including medical, dental and mental aid to needy transients To qualify for the receipt of any allotment, each state must submit plans for aid to transients to the Social Security Board and have them approved by that board

Foods, Drugs, Diagnostic and Therapeutic Devices and Cosmetics—Helium Gas H R 7494, introduced by Representative (now Senator) Hill of Alabama, and S 1567, introduced by Senator Sheppard of Texas, proposed to amend the act entitled "An Act authorizing the conservation, production, and exploitation of helium gas, a mineral resource pertaining to the national defense, and to the development of commercial aeronautics, and for other purposes" The purposes of both bills included the establishment of means by which helium gas not needed for military purposes might be sold for various civilian purposes, among them use for investigation and treatment of diseases The Senate bill was passed by Congress and approved by the President Sept 1, 1937 Regulations governing sales for medical and other nongovernmental uses have been approved by the President and were published in the Federal Register, Feb 26, 1938, pages 535-541 A summary appeared in THE JOURNAL, March 19, 1938, page 907

Cannabis H R 6906 was introduced by Representative Doughton of North Carolina "to impose an occupational excise tax upon certain dealers in marihuana, to impose a transfer tax upon certain dealings in marihuana, and to safeguard the revenue therefrom by registry and recording" This bill, which originated in the Treasury Department, proposed to regulate the possession, dispensing, administering and prescribing of cannabis and its preparations and derivatives along lines similar to those imposed on the possession, dispensing, administering and prescribing of opium and coca leaves, their derivatives and compounds, by the Harrison Narcotic Act The act was passed by Congress and was approved by the President Aug 2, 1937 Regulations promulgated under the act were published in the Federal Register, Oct 1, 1937, pages 2395-2407 A synopsis was published in THE JOURNAL, Oct 16 1937, pages 63B-64B

False Advertising of Foods, Drugs, Diagnostic and Therapeutic Device and Cosmetics S 1077 was introduced by

Senator Wheeler of Montana "to amend the act creating the Federal Trade Commission, to define its powers and duties and for other purposes" As introduced, it had no reference to foods, drugs, diagnostic and therapeutic devices and cosmetics, it related to them exactly as it did to all other merchandise It proposed to extend the jurisdiction of the Federal Trade Commission, which prior to the enactment of this bill covered only "unfair methods of competition in commerce," so as to make it extend to all "unfair or deceptive acts and practices in commerce" The bill passed the Senate and in the House of Representatives it was referred to the Committee on Interstate and Foreign Commerce, of which Representative Lea of California is chairman Representative Lea referred the bill to a subcommittee of which he is chairman also, which already had before it a mass of legislation relating particularly to foods, drugs, diagnostic and therapeutic devices and cosmetics, including in it S 5, the Copeland Food and Drugs Bill, which had passed the Senate In the end, the provisions for the regulation of the advertising of foods, drugs, diagnostic and therapeutic devices and cosmetics which appeared in S 5, the Copeland bill, were taken from it more or less attenuated, and then incorporated in the bill now under consideration The bill, known as the Wheeler-Lea bill, was then enacted with other modifications and was approved by the President, March 21, 1938 Its enactment means, it is believed, the exclusion of adequate advertising provisions to control the advertising of foods, drugs, diagnostic and therapeutic devices and cosmetics from any of the bills relating to merchandise of any of those kinds

Elixir of Sulfanilamide-Massengill S Res 194 was introduced by Senator Copeland of New York, requesting the United States Department of Agriculture to transmit to the Senate a full report of the facts concerning the deaths that then had recently occurred from the use of "a drug known as Elixir of Sulfanilamide" shipped in interstate commerce and to submit "recommendations for any needed legislation on the subject" This resolution was agreed to A similar resolution, H Res 352, introduced by Representative Chapman of Kentucky, was agreed to by the House

In response to the foregoing two resolutions, the Secretary of Agriculture submitted a report to the Congress with suggestions for legislation Those suggestions were embodied in S 3073, introduced in the Senate by Senator Copeland A bill to safeguard the public health, and in a bill, H R 9341, introduced in the House of Representatives by Representative Chapman of Kentucky, A Bill to safeguard the public health against the distribution of drugs not generally recognized as safe for use Both bills propose to prohibit any person from introducing or delivering for introduction into interstate commerce any drug the composition of which is such that the drug is not generally recognized, among experts qualified by scientific training and experience to evaluate the safety of drugs as safe for use under the conditions prescribed, recommended or suggested in the labeling thereof, unless such person holds a certificate issued by the Secretary of Agriculture showing that the drug has been tested and has not been found to be unsafe for use under such conditions They propose to set up the machinery whereby the Secretary of Agriculture can discharge the duties imposed on him The Senate bill has been favorably reported by the Committee on Commerce, to which it was referred, and is now on the Senate calendar The House bill was referred to the House of Representatives Committee on Interstate and Foreign Commerce and is still before that committee The subcommittee of the Committee on Interstate and Foreign Commerce that has the matter in charge is endeavoring to incorporate this bill in the remnants of the Copeland Food and Drugs bill, S 5

Surgical Ligatures and Sutures H R 6359, introduced by Representative Bernard of Minnesota, and S 1629 introduced by Senator Walsh of Massachusetts, propose to exclude from interstate and foreign commerce any surgical ligature or suture unless prepared at an establishment holding a license issued by the Secretary of the Treasury and contained in a package marked with the proper name of the article, the name of the manufacturer, and the date of manufacture and the date of expiration of the license, and the date of expiration of the license which the contents cannot be expected beyond reasonable doubt to yield their specific results These bills propose an amendment

to "An Act to regulate the sale of viruses, serums, toxins, and analogous products in the District of Columbia, to regulate interstate traffic in said articles, and for other purposes," approved July 1, 1902, and therefore were referred, respectively, to the House and Senate Committees on the District of Columbia.

No action has been taken on the House bill. The Senate bill was favorably reported and subsequently enacted by the Senate. It is now in the House of Representatives before the House Committee on the District of Columbia. Its enactment seems to be retarded by a desire on the part of certain persons in the Department of Agriculture to have jurisdiction over the production of surgical ligatures and sutures. The enactment of any pending legislation that gives the Secretary of Agriculture control over diagnostic and therapeutic devices will give him control over surgical ligatures and sutures, absorbent cotton, bandages, prosthetic apparatus of all kinds, surgical instruments and appliances, optical instruments and appliances, dental instruments and appliances, for they all come within the description of "devices" as that term is defined in pending bills. Strangely enough, too, one court has decided that a catgut ligature or suture is a "drug" and another has decided that a bandage is a "drug" within the meaning of the Federal Food and Drugs Act of 1906, as amended, decisions that are difficult for reasonable persons to follow.

Substitutes for Food and Drugs Act of 1906, as Amended. Six bills are now pending in the Congress, in addition to those referred to, to regulate the importation, production, manufacture, distribution and sale of foods, drugs, diagnostic and therapeutic devices and cosmetics. Only one seems to call for consideration here, S. 5, introduced by Senator Copeland of New York, passed by the Senate, and now pending in the House of Representatives, before the Committee on Interstate and Foreign Commerce. The advertising provisions of this bill as has been pointed out, were transferred in an attenuated form to the Wheeler-Lea Federal Trade Commission bill, S. 1077, which has been enacted. All pending bills relating to foods, drugs, diagnostic and therapeutic devices and cosmetics, except as has been described, are now before that committee and an effort is being made to evolve from them, chiefly from the remnants of the Copeland bill, S. 5, and the Chapman bill, H. R. 9341, proposing to restrict the exploitation of untried drugs, a general foods, drugs, diagnostic and therapeutic devices and cosmetics bill. The results of the activities of the subcommittee having the matter in charge have been embodied in a "committee print," Committee Print No. 4, but up to present writing the matter is still pending in the committee. The proposed legislation, as embodied in Committee Print No. 4, seems to give priority to the claims of importers, producers, manufacturers, distributors and dealers in drugs and diagnostic and therapeutic devices over the claims and interests of consumers, and it may be seriously questioned whether the enactment of legislation, such as is formulated in Committee Print No. 4 of S. 5, would accomplish any good purpose. This legislation has been discussed at length during the year in pamphlets that have been widely distributed throughout the country and to all federal senators and representatives, but apparently without effect.

Legislation Relating to Veterans—H. Res. 325, introduced by Representative Rankin of Mississippi, and agreed to by the House, Aug. 20, 1937, authorized the Committee on World War Veterans' Legislation or any subcommittee thereof to make a comprehensive survey and inspection of soldiers' hospitals and other veterans' administration facilities, including any hospital with which the government has a contract for ex-service men of any war in which the United States was engaged. The resolution required the committee to report its findings not later than Jan. 3, 1938. By H. Res. 408, however, introduced by Representative Rankin, and agreed to Jan. 28, 1938, the committee was given until Jan. 3, 1939, to complete its labors.

According to the Annual Report of the Administrator of Veterans Affairs for the year ended June 30, 1937, there were on that date under the control of the Veterans Administration 47,421 hospital beds and 16,225 domiciliary beds. Additions during the fiscal year 1938 will bring that number of hospital beds on June 30, 1938 up to 53,264 and the number of domiciliary beds up to 16,998. Present plans contemplate the addition in the fiscal year 1939 of 2,352 hospital beds, but 238 beds are

to be abandoned, so that on June 30, 1939, if present plans are carried into effect, the number of hospital beds at the command of the Veterans' Administration will be 55,378 and the number of domiciliary beds will be 19,397. No funds were appropriated for hospital and domiciliary construction during the fiscal year ended June 30, 1937, but the administration prepared and placed under contract certain projects approved for accomplishment from the \$21,250,000 appropriation made Aug. 12, 1935. On July 29, 1937, the Veterans' Administration Federal Board of Hospitalization approved the views and recommendations of the Administrator of Veterans' Affairs with respect to the matter of future policy concerning the construction of hospital facilities for veterans. Those views, as thus approved, were approved by the President, Sept. 20, 1937. The administrator states his views and recommendations as follows:

Essentially the new policy provides (a) for the acquisition of as many additional beds as may be required to meet the peak load of the N. P. group by including each year under a separate appropriation heading sufficient funds to provide the anticipated number of beds at the time such estimates are submitted; (b) that no additional beds be provided specifically for tuberculous cases, except as may be necessary to correct an unsatisfactory local condition or deficiencies; and (c) that no general construction program be undertaken for the general medical and surgical group but that additional beds for this type be provided in those areas where the available beds are disproportionate to the military population, such deficiencies to be met if possible through the use of other Government hospitals. *Annual Report of the Administrator of Veterans Affairs for the Year 1937* pages 3-4.

The Independent Offices Appropriation Act for the fiscal year ending June 30, 1939, carrying the appropriation for the Veterans' Administration, which is still in conference, proposes an appropriation of \$4,500,000 for additional hospital and domiciliary facilities for veterans. The act itself places no restriction on the character of the contemplated hospital construction, whether for general medical and surgical treatment or for tuberculous patients or neuropsychiatric cases. Its distribution will be determined, it is understood, by the policy of the administration outlined.

It is impossible to discuss in detail the various bills proposing appropriations for the construction of new hospitals for veterans. For general medical and surgical cases, 10,399 additional beds are proposed by thirty-nine bills, at a cost of \$43,385,000. For neuropsychiatric veterans, six bills propose to provide 1,894 additional beds, at a cost of \$6,950,000. For tuberculous veterans, two bills propose the construction of 400 additional beds, at a cost of \$860,000.

Contract and Acting Assistant Surgeons, Spanish-American War. H. R. 6498 was introduced by Representative Tinkham of Massachusetts, to provide pensions for persons who served under contract with the War Department as acting assistant or contract surgeons between April 21, 1898, and Feb. 2, 1901. Women nurses who served under contract as army nurses in the active military service of the United States between the dates named are already entitled to service pensions, that is, pensions incident not to disability incurred in line of duty but disability arising out of age. Contract surgeons and acting assistant surgeons who served under similar circumstances are entitled to pensions only for disability traceable to duty. This bill proposes only to make the pensionable status of contract surgeons and acting assistant surgeons the same as that of female nurses. The House Committee on Pensions gave a hearing on this bill, at which the Director of the Bureau of Legal Medicine and Legislation spoke in support of it. Up to the present writing, however, the committee has made no report.

Reorganization of the Executive Branch of the Federal Government. *United States Department of Health*—Six bills were introduced in Congress proposing the reorganization of the executive branch of the federal government. The general purport of these bills was the vesting in the President of authority to allocate and reorganize the several existing bureaus, divisions and offices of the executive departments. The bills propose the creation of a Department of Welfare but none suggest the creation of a Department of Health, nor was it possible to arouse in the Senate or the House the slightest interest in such a project.

H. R. 8202. A Bill "to provide for the reorganization of agencies of the Government, to establish the Department of

Welfare, and for other purposes," well illustrates legislative procedure with respect to bills proposing reorganization. The House of Representatives Select Committee on Government Organization has for some time past been studying the entire matter. On Aug. 10, 1937, without previously having held public hearings, Representative Warren of North Carolina introduced this bill. It was forthwith referred back to the Select Committee on Government Organization, by which it had been proposed. On the same day that it was introduced, August 10, it was reported back without amendment, with a recommendation that it pass. On August 13 it was passed and went to the Senate. In the meanwhile, in the Senate two committees had been engaged in a study of reorganization, a Select Committee to Investigate the Executive Agencies of the Government, the primary interest of which seems to be to incorporate economy and efficiency in anything that might be proposed, and a Select Committee on Government Organization, operating apparently for the purpose of bringing about a reorganization by the President. H. R. 8202, which had passed the House of Representatives, was referred to the latter committee, of which Senator Byrnes of South Carolina is chairman. Through his courtesy the chairman of the Association's Committee on Legislative Activities and the Director of the Bureau of Legal Medicine and Legislation were given fifteen minutes each wherein to present the views of the American Medical Association in support of the creation of a Department of Health, but the time allotted was materially abbreviated by questioning by members of the committee. That committee, August 17, reported to the Senate a bill, S. 2970 with the recommendation that it pass. Subsequently a redraft of this bill, S. 3331, was introduced by Senator Byrnes of South Carolina, referred to the Senate Select Committee on Government Organization and by that committee reported to the Senate, February 15, with amendments. The bill passed the Senate March 28 but further consideration by the House of Representatives is necessary before final enactment. So far as medical interests are concerned, and so far as relates to the establishment of a United States Department of Health, this bill does not differ materially from the bill passed by the House of Representatives.

H. R. 8202, one of the reorganization bills, which has passed the House of Representatives, and S. 3331, now being considered by the Senate, both provide for the establishment of a Department of Welfare, with a Secretary of Welfare at its head. An Under Secretary of Welfare and two Assistant Secretaries of Welfare are to be provided. The duty of the Secretary of Welfare is defined as follows in S. 3331:

Sec. 401 (c) The Secretary of Welfare shall administer the laws relating to any agency or function transferred to or brought within the jurisdiction and control of the Department of Welfare pursuant to law which relate to public health and sanitation, the protection of the consumer, education, the relief of unemployment and of the hardship and suffering caused thereby, the relief of the needy and distressed, the assistance of the aged, and the relief and vocational rehabilitation of the physically disabled.

United States Postgraduate Medical and Surgical College—H. R. 9687, introduced by Representative May of Kentucky, March 1, 1938, is a bill "to establish a United States Postgraduate Medical and Surgical College and Research Institute, to provide properly trained medical, surgical, and health personnel for the Military, Naval, and Public Health Services to coordinate and improve health research activities of the Federal Government, and for other purposes." The college, to be designated as an institute, is to be under the control and administration of a board of regents, consisting of the Surgeon General of the Army, the Surgeon General of the Navy, and the Surgeon General of the Public Health Service and four members appointed by the President. The college is to provide medical, surgical and clinical facilities for the diagnosis and treatment of all types of illness, physical and mental disabilities for any person whose annual income is not in excess of \$1,000, except in police cases and in cases of emergency arising from accident. It is to establish and maintain a course of training and research in medical and surgical science and public health open to graduates of accredited medical and surgical colleges seeking training for army, navy and public health work, on designation of senators and representatives. The training is to extend over

a period of three years, students receiving \$1,200 a year while in training. Graduates are to have a preferred status in vacancies in the Army, Navy, and Public Health Service and must serve in one of the three services for four years, in which vacancies occur. This bill was referred to the House Committee on Interstate and Foreign Commerce, where it now is.

SOCIAL SECURITY AND INCOME TAXES AND STATE AND COUNTY MEDICAL ASSOCIATIONS

The fact that state and county medical associations might be liable for taxes under the Social Security Act and were required to prove their right to exemption brought to light the fact that many such associations were unaware of the possibility of a similar tax liability and obligation under the Federal Income Tax Acts. Such acts for many years past have imposed certain income taxes on associations and corporations generally and have then exempted certain classes of such organizations. The exemption, so far as state and county medical associations are concerned, is as follows:

"The following organizations shall be exempt from taxation under this title—

(6) Corporations, and any community chest fund or foundation organized and operated exclusively for religious, charitable, scientific, literary, or educational purposes or for the prevention of cruelty to children or animals, no part of the net earnings of which inures to the benefit of any private shareholder or individual and no substantial part of the activities of which is carrying on propaganda or otherwise attempting to influence legislation."

Income Tax Act of 1936, Section 101 (6)

The Commissioner of Internal Revenue, who is charged with the duty of collecting the federal income tax, has by regulation required that an organization claiming exemption shall file its claim with the collector of internal revenue in the collection district in which such organization will be required to pay income taxes if it is not tax exempt.

The general plan of tax liability for state and county medical associations under the Social Security Act is similar to that under the Income Tax Act, as set forth, except that exemption from tax liability under the Social Security Act does not depend on the nature and extent of the association's attempts to influence legislation. The Commissioner of Internal Revenue, who is charged with the duty of collecting taxes under the Social Security Act, has held that an organization that has established its tax-exempt status under the section of the Income Tax Act quoted will be presumed to be exempt under the Social Security Act also, but obviously the contrary is not necessarily true. An organization whose activities are substantially in the field of propaganda to influence legislation might be barred from exemption under the Income Tax Act and yet not barred under the Social Security Act.

The Bureau of Legal Medicine and Legislation has brought this matter to the attention of the several state medical associations and has given them full instructions as to procedure for themselves and their respective county medical societies. Some of them have established their tax-exempt status, but how generally efforts have been made toward that end and how successful such efforts have been is not known. The situation should receive the serious consideration of state and county medical associations, in order that they may bring themselves within the tax-exempt class if they are not already there and thus prevent the accumulation of taxes and tax penalties that must ultimately be paid.

SOCIAL SECURITY TAXES AND THE PHYSICIAN

The year 1937 marked the beginning of the active duties of physicians, together with all other taxable employers, under the Federal Social Security Act. The act imposes on employers, with certain exceptions, two distinct payroll taxes. With respect to these taxes a physician stands in a position no different from that of any other employer. Even the fact that his employees are physicians is not material. One tax is imposed only on employers of eight or more and is designed to provide so-called unemployment compensation for workers eligible for such benefits. The other tax is imposed on an employer and employee alike, even though there is only one employee, and is designed

to provide old age annuities for such workers as may ultimately be entitled to them. Not only must every physician employing one or more persons—as, for instance, another physician acting as his assistant on a part time or full time basis, or a nurse, or a reception clerk—pay this tax, but he must collect and remit to the collector of internal revenue the tax payable by his employees. The Bureau of Legal Medicine and Legislation, through editorials, comments and special articles published in THE JOURNAL, has endeavored to guide the medical profession through the mazes of their tax liability. Its efforts seem to have borne fruit, judging from the diminished number of requests recently received from physicians for advice and guidance with respect to these taxes.

STATE LEGISLATION

Through a legislative reporting service, the Bureau of Legal Medicine and Legislation receives daily when any state legislature is in session notices of bills of interest to the medical profession that have been introduced. Ordinarily such notices are received about the third day after the introduction of the bill and consist of only the number and title of the bill, the name of its sponsor, and the title of the committee to which it has been referred. Obviously, a state medical association that maintains its own legislative service at the state capital or has its headquarters there usually obtains such information more promptly than can the Bureau of Legal Medicine and Legislation in Chicago, but most of our state associations are not so fortunately situated. The Bureau, therefore, immediately on receipt of notice that a bill has been introduced reports its introduction to the president, the secretary and the chairman of the legislative committee of the state association immediately concerned. This reporting in triplicate enables the officers named to confer among themselves at once to determine the policy of their association with respect to the measure.

As soon as possible after the introduction of a bill, our legislative reporting service supplies a copy of it, and it is then analyzed by the Bureau in the light of the laws already in force in the state and of the policies of the American Medical Association. If the analysis shows anything of moment that may escape the attention of the officers of the state medical association, a letter stating the facts is immediately sent to the secretary of the association, copies of which are sent to the president and the chairman of the legislative committee, for their guidance. In any event an abstract of each bill is submitted to THE JOURNAL for publication, so that every Fellow of the Association and every subscriber to THE JOURNAL may know what legislation is pending in his own state. In this way, interested Fellows and members of the Association in every State, and subscribers to THE JOURNAL, learn what is going on more promptly than would otherwise be possible, for the state journals, with possibly a very few exceptions, appear only monthly whereas the service rendered by the Bureau, through THE JOURNAL, is weekly. A similar service is rendered as the bill progresses toward defeat or enactment, the Bureau receives from its legislative reporting service reports of action by committees and by either branch of the legislature and of the enactment or defeat of the bill, if it reaches a final vote. As has been pointed out, although a few state medical associations are so highly organized and fortunately situated as not to be in need of such service as is described to a large number of such associations the service seems to be of value.

After the close of each calendar year, the legislation that has been considered by state legislatures that met during the year is summarized and the result published in THE JOURNAL to keep the medical profession of the country informed of the trends of legislation and legislative opinion in the various legislative fields of medical interest and of the successes and the failures of the several state associations in promoting or defeating legislation in which they severally have been interested. The summary of state legislation for 1937 was published in the Organization Section of THE JOURNAL February 5, 12 and 19 of the current year. A brief discussion of some of the more important state legislation considered during 1937 follows:

Laws Relating to the Healing Art—Basic science acts were passed in 1937 in Colorado, Michigan and Oklahoma. Unfortunately the boards of examiners authorized by the Colorado and Oklahoma laws each include a physician, an osteopath and a chiropractor, and not such truly nonsectarian boards as a basic science law usually provides. A chiropractic practice act was passed in Delaware, and chiropractors there are now licensed by an unsupervised and uncontrolled board of chiropractic examiners, without even such restraint as a basic science law might impose, for Delaware has no such law. With respect to naturopaths a similar situation exists in South Carolina, where a naturopathic practice act was enacted and an independent naturopathic licensing board created. Medical practice acts were amended or supplemented in Arkansas, California, Connecticut, Delaware, Kansas, Minnesota, Nebraska, Nevada, New Hampshire, Oregon, Pennsylvania and Vermont. Osteopathic practice acts were amended in Kansas, Michigan, Missouri, North Carolina and Pennsylvania. Chiropractic practice acts were amended or supplemented in Connecticut, Florida, Idaho, New Hampshire, North Carolina and Oklahoma. Details concerning all such legislation can be found in the Organization Section of THE JOURNAL (Feb 5, 1938, pp 59B-67B).

Medical and Hospital Lien Law—A lien law was enacted in the state of Washington which authorizes liens for physicians and hospitals treating and caring for persons injured through the negligence of others. The authorized liens may cover on all rights of action, claims, judgments or compromises accruing to the patient because of his injury.

Health Insurance—Bills proposing the establishment of systems of compulsory state health insurance were considered in 1937 in Massachusetts, New York, Pennsylvania, Rhode Island and Wisconsin, but not one was enacted. All were patterned closely after the so called Epstein social security bill for health insurance.

Narcotic and Hypnotic Drugs—The uniform narcotic drug act with but little modification, was enacted in 1937 in Arkansas, Michigan, Minnesota, Missouri, Montana, Nevada, Tennessee, Texas and Wyoming. Thirty-two states have now adopted legislation conforming substantially to the uniform act. Bills masquerading as the "uniform narcotic drug act," but differing from it in important particulars were enacted in Idaho and Iowa. Neither of these laws limits to any stated amount the quantity of opium and coca leaves and their derivatives and compounds that a person can buy without a prescription provided he purchases the drug in so called exempt preparations. Similarly impotent laws have been enacted in five other states since 1934. So widespread has been this movement toward emasculating narcotic legislation that a question arises as to whether it has not been directed from some central agency interested in removing restraint from the sale of the narcotic drugs named. The distribution of narcotic drugs through so-called exempt preparations has assumed such proportions as to call for drastic measures to curb it, rather than to justify or excuse any breaking down of the law in order to facilitate the widespread sale of such preparations.

The uniform narcotic drug acts in force in Nebraska, New Mexico and South Carolina were amended in 1937 so as to classify cannabis among the narcotic drugs covered by them. In Arkansas and Tennessee laws were enacted prohibiting the possession sale or distribution of cannabis so called marijuana, except sale and distribution on the written prescription of a physician, dentist or veterinary surgeon.

The sale and dispensing of certain hypnotic and somnifacient drugs were limited by law in two states in 1937 to sales and dispensing on the prescription of licensed physicians, dentists and veterinarians. In Rhode Island the restrictive law covers barbital, trional, sulfonal, tetralol, carbomal, paraldehyde, chloral or chloral hydrate and chlorobutanol. In the South Carolina law barbiturates or barbiturate compounds are named. A Texas law imposing limitations on similar sales was repealed.

Hospital Service Corporations—Corporations to provide hospital care for their members and subscribers on a so called nonprofit basis were enacted during the year in California, Georgia, Maryland and Pennsylvania.

Workmen's Compensation—Legislation relative to occupational diseases was enacted in Delaware, Indiana, Michigan, Ohio, Nebraska, Pennsylvania and Washington. The Indiana act provides compensation for disability resulting from any occupational disease arising out of and in the course of employment. The laws of the other states named include lists of the diseases for which benefits may be paid. Laws increasing the medical, surgical and hospital service to be rendered at the employer's expense were enacted in Indiana, Iowa, Kentucky, Pennsylvania and Rhode Island. Pennsylvania and Vermont, by laws enacted in 1937, permit an injured workman to select his own physician under certain stated conditions.

Eugenic Marriage Laws—Laws requiring as a condition precedent to the issue of a marriage license that both parties to the proposed marriage present certificates of freedom from venereal disease, signed by physicians, were enacted in 1937 in Illinois, Michigan and New Hampshire. Prior laws in Oregon and Wisconsin, requiring such certificates from prospective bridegrooms only, were amended to require similar certificates from the prospective brides also.

Vaccination—Successful immunization against smallpox and diphtheria was made a condition precedent to the admission of children to school by a West Virginia statute enacted during the year.

Contraception and Venereal Disease Prophylactics—California, Idaho, Nebraska and Utah during the year prohibited by law the sale or other distribution, except by a licensed physician or by a licensed pharmacist, of appliances, drugs and medicinal preparations intended or having special utility for the prevention of conception and of venereal diseases. These laws limit generally the sale of such appliances, drugs and preparations to such as have been approved and listed by some designated state agency as conforming to the standards of quality and labeling stated in the law.

STATE LEGISLATION BY INITIATIVE

The constitutions of some states, chiefly states in the West and the Southwest, provide for the enactment of legislation by the people directly, through their own votes at the polls, by what is sometimes referred to as the initiative system, so as to enable them to evade the considered judgement of their elected representatives in their respective legislatures. In those states too that authorize legislation through the initiative, provision is made also by means of the referendum for overriding the action of the legislatures by referring to the electorate at the polls measures that may have been enacted by the legislature, thus giving the electorate a chance to reverse the action of its elected legislators. Procedures under the initiative and referendum have been resorted to on several occasions heretofore, generally to accomplish some purpose that did not and would not appeal to the best judgment of the legislature. The chiropractic practice act and the osteopathic practice act of California were enacted in this way in 1922, and under the constitution of the state can be changed only by another initiative procedure, in that state the legislature is powerless to afford relief against a law enacted through the initiative, but if relief is to be obtained it must be obtained through another initiative. In 1922 also an initiative in California to prevent animal research, was defeated through the energetic action of the California Medical Association. More recently the chiropractors of Oregon endeavored through the initiative to organize a radical and an entirely new system of control of the practice of the healing art that would have broken down all safeguards, but the electorate of that state promptly defeated the measure. At the present time initiative measures are pending or have recently been disposed of in three states: California, Colorado and Oklahoma.

In Colorado an initiative measure was proposed by the chiropractors of the state to remake the laws of the state relating to the practice of the healing art. Through the vigorous action of the Colorado State Medical Society, it was demonstrated after the petition had been presented to the secretary of state for incorporation in the ballot that is to be presented in November next, that many of the signatures on the initiative petition were forged and that there were other substantial

irregularities. Proof of such irregularities in the initiative petition barred the proposed initiative measure from the ballot, and by the time the proof was offered it was too late for the proponents of the proposed initiative measure to go over the field and to correct their mistakes, even if they had been otherwise able to do so. The Colorado initiative has therefore been definitely defeated for the present.

In California the pending initiative measure is designed to hinder the use of living dogs for purposes of research. It proposes to forbid the delivery of any living dog from any person in the state to any institution of learning or research for purposes of study or instruction. The people of the state have formed an organization to combat the arguments of the proponents of this measure, and the issue will be fought out at the polls in November next.

In Oklahoma the initiative proposes, principally, so to amend the medical practice act as to permit hospitals and clinics organized on a mutual or cooperative basis to enter into contracts for hospital or medical services and to prevent the board of medical examiners from disciplining licensed physicians who cooperate in such schemes.

MALPRACTICE

The American Medical Association is without exact information concerning the frequency of demands on physicians and of suits against them, for damages alleged to have been suffered by reason of malpractice, or of the causes and results of such demands. In the absence of such information, advice as to measures of prevention must be based on speculation rather than fact, and there is no available method for determining the results of such advice.

Some medical associations have interpreted the ruling of the joint committee made up of members of the Committee on Ethics and Grievances and the Committee on Unauthorized Practice of the American Bar Association, in the Ohio State Medical Association case, as barring a medical association from cooperating at all with members in defense against malpractice suits. That is not the case. So long as the medical association limits its activities to the medical aspects of the case, it is certainly within its rights. The medical association which is entitled to legal aid in determining its own course. The line of demarcation comes if and when it undertakes to determine for the member who has been made the victim of a demand or a suit the attorney whom he shall employ or to aid that attorney by furnishing legal assistance. It is believed that a properly organized committee on grievances, by whatever name it may be known, can properly hear the evidence of a member who has been threatened with a suit or is being sued and of such witnesses as he may desire to produce. It may hear also if the patient is willing, the patient and such witnesses as he may offer. The committee for the medical association can then, with the assistance of its own counsel, determine for its own guidance whether the physician involved in the case exercised due diligence, ordinary knowledge and skill, and his best judgement, and whether he respected the patient's confidence within the limits required by good professional practice. In the light of the information thus gained the medical association can determine whether it will or will not cooperate with the physician through the furnishing of expert medical witnesses and, it may be, an expert medical assistant for counsel. Such a committee can also keep a record of such claims and suits as are brought to its notice and of the ultimate results, can attend trials, and can generally study and investigate the malpractice situation within its own jurisdiction, including insurance rates and methods of insurance companies, and it then can determine what action can be best taken to limit the number of malpractice suits and the amounts of damages awarded.

ANIMAL EXPERIMENTATION

The District of Columbia has no legislature. Its board of commissioners has limited authority in the way of making regulations, but laws for the District are enacted by Congress. In its capacity as legislature for the District of Columbia the Congress has the following two bills before it: H. R. 11818, introduced by Representative Quinn of Pennsylvania, and S.

propose "to prohibit experiments upon living dogs in the District of Columbia" The Senate bill was referred to the Senate Committee on the District of Columbia, where it now is The House bill was referred to the House Committee on the District of Columbia and a hearing has been held on it, but the committee has made no report The purpose of these bills is, it is understood, to provide an entering wedge whereby, after experimentation on living dogs has been prohibited, experimentation on all other animals will in like manner be prohibited and whereby, after any legislation of this class has been enacted by Congress for the District of Columbia, efforts will be made to procure similar legislation in the several states, the legislatures of which will supposedly be greatly impressed with the fact that Congress has enacted a law of this type

As noted, an initiative measure is pending in California that if enacted will hinder the use of dogs for experimental purposes

COOPERATION APPRECIATED

On behalf of the Bureau of Legal Medicine and Legislation, the Board of Trustees expresses appreciation of the cooperation that the Bureau has received from the several state and county medical associations of the country and from individual physicians

Summary

1 Federal Legislation—(a) Since the last report of the Board to the House of Delegates, the Congress has enacted the National Cancer Institute Act, the Marihuana Tax Act of 1937, An Act authorizing the Bureau of Mines to manufacture and sell helium gas for medical and other nongovernmental uses, and an act devolving on the Federal Trade Commission jurisdiction over the advertising of foods, drugs, diagnostic and therapeutic devices and cosmetics

(b) Five proposals are pending contemplating either a federal investigation concerning health insurance or the enactment of definite schemes for the establishment of health insurance No action has been taken on any of these proposals Another similar measure proposes the establishment of a United States Postgraduate Medical and Surgical College to provide not only postgraduate courses in medicine but also medical and surgical services for persons whose annual incomes are not in excess of \$1,000 An investigation of the activities of the American Medical Association and of state and county associations in connection with Group Health Association, Inc., is proposed by a pending resolution

(c) Bills are pending, some of which are receiving consideration, contemplating federal subsidies to aid the states in general health activities, in the medical care of transients, and in the control of venereal diseases and tuberculosis Other federal proposals contemplate the establishment of hospitals for the "medically needy," the use of federal moneys for the prevention and cure of infantile paralysis, blindness, deafness and other social diseases, and the regulation of interstate commerce in goods produced under conditions exposing employees to the hazards of silicosis and related dust diseases

(d) After the Copeland food and drugs bill, S 5, was stripped of all provisions relating to advertising and they were transferred to the Federal Trade Commission bill that was enacted, efforts were begun to evolve a new measure from the remnants of the Copeland bill and from other proposals relating principally to drugs not generally recognized as safe for use Indications are that the new measure may possibly give priority to the interests of importers, producers, manufacturers, distributors and dealers over the interests of consumers

(e) The House Committee on World War Veterans' Legislation is continuing its investigation of veterans' hospitals At the same time proposals for the construction of additional hospital facilities for veterans of the World War continue to increase The discrimination that has long existed against contract surgeons of the Spanish-American War remains uncorrected

(f) Efforts to arouse interest in the establishment of a Federal Department of Health have been unproductive Pending reorganization proposals contemplate the creation of a Department of Welfare in which will be grouped the health activities of the government

(g) Legislation proposing to prohibit experiments on living dogs in the District of Columbia is pending If this legislation is enacted it will serve as an entering wedge and will facilitate the enactment of similar legislation by the several states

2 Social Security Act—State and county medical associations are subject to the taxes imposed by the Social Security Act and by the Federal Income Tax Act unless they establish their exempt status to the satisfaction of the Commissioner of Internal Revenue Individual physicians, if employees or employers, are subject to the social security taxes

3 State Legislation—(a) Through a legislative reporting service the Bureau keeps constantly in touch with state legislation of medical interest and promptly advises state associations of legislative proposals of particular medical interest New basic science laws were enacted in Colorado, Michigan and Oklahoma Compulsory state health insurance proposals were made, but not enacted, in Massachusetts, New York, Pennsylvania, Rhode Island and Wisconsin Other legislation of medical interest enacted in one or more states relates to narcotics, medical liens, hospital service corporations, eugenic marriage, vaccination, contraceptive devices, chiropractic, naturopathy, osteopathy and medical practice acts generally

4 Initiative Measures—In states where the enactment of legislation by the people directly through the medium of the initiative measure is possible, opponents of scientific medicine are seeking to give effect to this opposition through the approval of initiative measures by the people Colorado defeated a chiropractic initiative proposal that would have utterly disrupted the medical licensure scheme in the state Other initiative measures are pending in California, to prohibit the use of living dogs for experimental purposes, and in Oklahoma, to permit, among other things, hospitals and clinics to enter into contracts for the supplying of medical care

5 Malpractice—State medical associations can and should assist members against whom unjust claims based on alleged malpractice are made Such assistance, however, should be so confined as to avoid any encroachment on the field of the practice of law

Bureau of Health and Public Instruction

RADIO PROGRAM

An important activity of this Bureau is that concerned with a weekly broadcasting program carried out with the fine cooperation of the National Broadcasting Company The dramatized radio program initiated in 1935 finished its second successful season in June 1937, with a series of broadcasts based on the annual scientific assembly at Atlantic City The weekly broadcasts dealt with various subjects under the head of "Medical Emergencies and How They Are Met" In October 1937 a new type of program was undertaken—a special program keyed to the needs of health classes in senior and junior high schools Education by radio has progressed from the technic of merely broadcasting material at the listener and hoping that it may do some good to recognition of the fact that the best programs are what are known as 'participating' programs, whereby the listener's interest is enhanced and his chances of learning are increased through doing something instead of merely listening

It was apparent from a general knowledge of the health education situation in schools, that at the high school and junior high school age level existed the greatest need and therefore the greatest opportunity for supplementing health

teaching in the schools, by means of a dramatized radio program with appropriate supplementary material through which participation could be stimulated. HYGIEIA seemed the logical channel for the publication of such supplementary matter. The Board of Trustees authorized such a program. A radio supplement department was inaugurated in HYGIEIA in October 1937 timed and coordinated with the radio dramatizations for that month. This has been continued each month. The HYGIEIA material consists of briefs of the four programs constituting the group to be broadcast during the month corresponding with each issue of HYGIEIA.

Shortly after the program was publicly announced the New York office of the National Broadcasting Company sent a representative of the Johnson Publishing Company, Richmond, Va., to the American Medical Association to inquire about publishing and distributing to the schools a workbook for the use of pupils listening to the program. Such a workbook was prepared by Drs. Bauer and Teschner and published by the Johnson Publishing Company, the publisher to undertake its distribution in the schools.

At the end of 1937, twelve programs in the series had been broadcast and a great deal of interest had been shown by educators. Public schools in a number of communities, including New York City, were using the program. Deputations from the State Department of Health of Illinois, from the Chicago city schools and other groups representing educators had visited the studios and witnessed the broadcasts. The evidence at hand is to the effect that the program as conceived fills a real need in the health curriculum of junior and senior high schools and that it has not lost its appeal to adult listeners outside the schools. The broadcasts for the fall and winter season of 1938-1939 will begin earlier than heretofore.

The radio library of the American Medical Association, which is maintained for the use of state and local medical societies, and organizations whose use of the material such societies are willing to sanction, has been used more heavily this year than in 1936, the number of scripts distributed being 4,589 for 1937 as compared with 3,388 in 1936. In 1937, seventy-two county medical societies used the scripts as compared with thirty-four in 1936, and thirteen state medical associations as compared with five in 1936.

The scripts have been kept up to date by dropping seventy-six older manuscripts and adding sixty new ones, leaving a total of 867 titles, of which 365 are for fifteen minutes, 188 for ten minutes and 300 for five minutes.

PROTECTION OF RESEARCH

The principal activity of those who oppose the use of animals for the purposes of research, aside from routine publications and propaganda, continues to be centered in Massachusetts and California, though effort has been made to secure the enactment by congress of legislation to apply to the District of Columbia.

For several years California antivivisectionists have been attempting to render impossible the use of dogs and cats from public pounds. Failing to get legislation through ordinary channels, they have resorted to the initiative provided for in California law. A petition for a so-called Humane Pound Law was circulated and received sufficient signatures to insure a place on the ballot for a vote in November 1938. The law as drawn would provide that medical schools or organizations participating in medical research could not receive dogs or cats from public pounds. Such a law would cripple medical research. Moreover, it is merely an entering wedge. Instead of covering only cats and dogs it would soon include, by amendment, all other animals. On the basis of success in California, the antivivisectionists would soon be seeking similar legislation in other states and, because of success in California, would be more liable to succeed elsewhere. The American Medical Association Committee for the Protection of Medical Research and this Bureau have attempted to be as helpful as possible in opposing the enactment of the so-called Humane Pound Law.

The Bureau made its usual donation in May to graduating medical students of complimentary copies of the pamphlet

Animals in Research, including the article "The Dogs Go to the Relief of Suffering," by Cannon and Drinker and "The Ethics of Animal Experimentation" by John Dewey.

COOPERATION WITH LAY ORGANIZATIONS

National Congress of Parents and Teachers—Progress continues toward more widespread use in many localities of the physicians' own offices for the examination of children in the Summer Round Up. More localities are making arrangements to have physicians paid for their services as examiners. As authorized annually by the Board of Trustees, 300,000 examination blanks were printed, of which one half were donated by HYGIEIA, the Health Magazine, and the other half by the national Congress.

At the annual meeting of the Advisory Committee for the Summer Round-Up, the following resolution was adopted:

Glasses should not be fitted on the basis of such an examination (the eye examination in the Round Up). An adequate examination for diagnosis of eye disease or defects of vision or to determine the necessity for glasses can therefore be performed only by a licensed physician.

During the year a survey was conducted by the Bureau of Health and Public Instruction of the opinions of fifty widely scattered general practitioners personally known to the Director with relation to the blank used in the Summer Round Up of the Children. A few complaints had been received to the effect that the blank was too time consuming. A survey of opinion, however, brought forth thirty-five replies out of fifty letters and, of these, twenty endorsed the blank as it stood and fifteen recommended various changes, none of them of major significance. Only one letter indicated opposition to the whole idea of the Summer Round-Up, designating it as an approach to state medicine.

General Federation of Women's Clubs—A meeting of the advisory committee was held at Washington in October. The meeting was largely routine. A special intra organization program was planned for educating the club women in syphilis. Routine progress was reported in the cancer education campaign, the maternal and child welfare campaign and other health interests. The community health study was reported to have attracted practically no attention among local women's clubs after the first year (1935).

4-H Clubs—At a meeting of the National Committee for Boys' and Girls' Club Work, better known as 4-H Clubs, in December 1937 there was offered rather severe criticism of the committee and its methods with special reference to unwarranted handling of the "healthiest boy" and "healthiest girl" contests local, state and national. The Director of the Bureau, as a member of the committee, had previously offered objections to the methods used. This new criticism came from a subcommittee representing the United States Department of Agriculture and the Association of Land Grant Colleges.

During the year the Director of the Bureau challenged the authenticity of certain statements in relation to tuberculosis published in *4-H Club News* without consultation with the only physician on the committee, namely, the Director of the Bureau. It has been agreed that subsequent statements, medical in character or having a medical bearing, will be submitted for approval prior to publication.

Joint Committee on Health Problems in Education—The Joint Committee representing the National Education Association and the American Medical Association, under the chairmanship of Thomas D. Wood, M.D., has continued its work.

The principal activity in 1937, aside from the publication of routine technical reports, was the organization of a symposium on school health problems in connection with the meeting of the American Medical Association at Atlantic City. This symposium, though arranged too late to receive a place in the printed program of the American Medical Association meeting, nevertheless attracted several hundred physicians and the proceedings were published in their entirety in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*. This is the first program connected with the Joint Committee's work which has been a part of the American Medical Association meeting. Its success indicates the desirability of repeating it if not annually at least frequently.

During 1937 the American Physical Education Association, an organization of teachers of physical education and of athletic coaches and including some physicians, became merged with the National Education Association Department of Health and Physical Education. The new organization is known as the "American Association for Health and Physical Education"—A Department of the National Education Association." It is organized in three coordinate divisions dealing respectively with physical education, health and recreation. In each division are special sections. The medical section is in the division of health. Membership in the section is limited to members of the American Medical Association in spite of the fact that effort was made at the meeting to open the membership of the section to physicians employed in school health work even if not members of their local medical societies.

American Public Health Association—The Director of the Bureau, having finished his term as chairman of the Section on Health Education of the American Public Health Association, remains for five years a member of the section council. Relationships of the Bureau with the section are quite satisfactory.

United States Children's Bureau—Very little complaint has been received at headquarters relating to the functioning of Social Security health programs administered by state health departments under grants from the Children's Bureau. The attitude of present officers of the Children's Bureau is apparently friendly and cooperative. It appears that efforts will be made to enlarge the appropriation for maternal and child health work as indicated in a conference called at the Children's Bureau (October 19) at which opinion of representatives attending was solicited as to the advisability and necessity of larger child health and maternal health appropriations.

American Social Hygiene Association—The outgrowth of the interest in syphilis dramatized by Surgeon General Parran on his appointment to be surgeon general of the United States Public Health Service continues at a high level. A number of books on the subject have appeared. *HYGEIA* has carried numerous articles, some of which have been made into reprints and are selling fairly rapidly. A National Social Hygiene Day was held in February 1937, being devoted largely to public addresses and articles in newspapers on the topic of syphilis. A second Social Hygiene Day is planned for February 1938 for the purpose of raising \$500,000 to support the increased demands for services on the American Social Hygiene Association. In this project, state medical societies and local medical societies are being asked to participate. The Bureau has attempted, through the columns of the Organization Section of *THE JOURNAL*, to keep the profession informed relative to genuine versus pseudo social hygiene organizations.

COOPERATION WITH STATE AND COUNTY SOCIETIES

The Bureau continued, as in the past to cooperate with county medical societies and with outside organizations by attempting (a) to function as a clearing house for health information and ideas and (b) to establish and further cordial relationships between the medical profession and other organizations working for similar purposes. For these purposes the Director and the Assistant Director attended twenty conference meetings.

PERSONAL APPEARANCES

Personal appearances made by the Director in 1937 totaled eighty-seven addresses in addition to conferences attended. The Assistant Director made thirty-eight addresses. The total was 125. This is 36 per cent greater than in 1936. These appearances involved practically 40,000 miles of travel by railroad, automobile and busses. Appearances were made in twenty-four states. Forty engagements had to be declined because of conflicting schedules and for other reasons.

HYGEIA CLIPPING AND LOAN COLLECTIONS

The clipping loan service of *HYGEIA* material made into convenient collections and accompanied by a proposed outline for a speech continued in 1937 to be a notable success. The number of loan collections sent out in 1936 was 230 and the distribution covered thirty-eight states. In 1937 the distribution was 375 collections. In two years physicians in every state in the union

have been served, except in Maine and Nevada. The state of New Jersey, with the aid of recent back numbers of *HYGEIA* and of pamphlets of the Bureau of Health and Public Instruction, Medical Economics and Investigation, has established its own loan collection service for physicians within the state and indications are to the effect that the Philadelphia County Medical Society will do the same thing in the same way. The Bureau will cooperate by referring to the appropriate local chairman all requests from New Jersey and, perhaps, from Philadelphia. This decentralization will reduce the apparent service rendered by the Bureau direct, but it is believed that it represents sound organization policy.

BUREAU PUBLICATIONS

The pamphlet publications of the Bureau were maintained as in past years by revising, dropping or adding as demand seemed to indicate.

The director of the Bureau contributed eighteen items and the Assistant Director three items to *THE JOURNAL* in 1937, including one editorial, eight current comments, one news item, two queries and minor notes, and nine items for the Organization Section. The Symposium on Health Problems in Education arranged at the Atlantic City session on behalf of the Joint Committee was published in full.

Publications originating in the Bureau but appearing in periodicals published elsewhere included twenty-seven magazine articles.

EXHIBITS

The Bureau cooperated, as in former years, with the Bureau of Exhibits in the preparation of exhibit material for use on various occasions.

The Bureau continues to furnish material for the numerous local traveling exhibits prepared by the American Medical Association Bureau of Exhibits and receives in return much valuable assistance from the Bureau of Exhibits. Close cooperation between the two bureaus is maintained at all times.

During 1937 the Directors of the two bureaus collaborated in preparation of a book entitled *Health Education of the Public*. With a foreword by the Editor of *THE JOURNAL*, this book was published by the W. B. Saunders Company.

Summary

The work of the Bureau of Health and Public Instruction has proceeded along established lines but reached a high peak in 1937. The dramatized radio program conducted with the cooperation of the National Broadcasting Company completed its second successful season in 1937. The nature of the program was changed in that it was particularly directed to the needs of students in senior and junior high schools, though an effort was made to maintain appeal to general public audiences. The radio library of the Bureau has been maintained for the use of state and local societies, and the library material was much more widely used in 1937 than in any preceding year.

The Bureau has cooperated as fully as possible with official agencies concerned with the protection of scientific research.

The Director of the Bureau has served as a member of official committees of a number of important lay organizations, including the National Congress of Parents and Teachers, the General Federation of Women's Clubs, the 4-H Clubs, the Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association, the Children's Bureau of the U. S. Department of Labor and other important organizations. The Bureau has also cooperated closely with the Bureau of Exhibits in the preparation of exhibit material.

The Director and the Assistant Director of the Bureau have appeared before a larger number of public audiences than in any previous year. The educational publications issued under the direction of the Bureau have been widely distributed. The number of inquiries received from lay persons increased during the year by approximately 15 per cent.

Bureau of Medical Economics

The movement toward the socialization of the necessities of life has thus far concerned itself almost entirely with but one of those necessities—medicine. Those who propose various devices to socialize medicine seem to assume that a very large percentage of the population is not receiving needed medical care. It is also assumed by these social reconstructionists that radical changes in the methods of distributing medical services are necessary if those who are not now receiving medical care are to be provided with such care. Moreover, these same reformers, many of whom are not medically trained, believe that the radical changes which they urge can be made without affecting the quality of medical care, without disrupting the processes of medical education and research, and without disturbing the close personal relationship between the patient and his physician—all of which are essential to medical progress and continued improvement in public health.

It appears that the proponents of drastic departure from the course of private medical practice are interested chiefly in the methods of organization, distribution and control of medical services which will provide a greater abundance of cheap medical care. They fail to consider the inevitable result which the cheapening and mechanization of medical services will have on the prevention and relief of illness. None of the utopian schemes that have been proposed, except a system of complete state medicine, would include all income groups of the population. Thus the problem of providing medical services for the indigent, the unemployed and those suffering from certain chronic conditions would remain as a separate task to be met and financed in an entirely different manner.

The many health and medical surveys made during recent years have recorded various percentages of the population in need of medical care. If these percentages are accepted as reasonably correct, only from 5 to 10 per cent of the population appear to be in need of medical care which, presumably, they are not now receiving. These studies also reveal that about one half of the population report no illnesses in any one year. The amount of medical services which this apparently well half of the population might properly use cannot be accepted as a condemnation of the present method of providing medical services. This is evidenced by the fact that more than 90 per cent of the persons in the sick half of the population are attended by physicians. Further evidence is the constant decrease in morbidity and mortality rates, which makes the United States one of the most healthful countries in the world. If interpreted literally, these figures do not present an appalling lack of medical care such as is usually reported by proponents of new methods of medical practice, who state that from one fourth to one half of the population is not receiving needed medical services. The available figures which purport to show the unfilled need for medical care and the statements made by many social reformers are obviously in sharp disagreement and prompt some queries as to the accuracy and source of information.

The American Medical Association has consistently maintained an interest in the availability and the quality of medical services. The several councils and bureaus of the Association have as their central function the protection of the quality of medical service by an appraisal of the various elements entering into that service. The American Medical Association has held itself ready and willing to discuss with qualified agencies the questions of need for medical services and the appropriate means to provide such needs. Thus far, only one direct official request for such a discussion and coordination of effort has come to the Association—that from the American Public Health Association.

STUDY OF MEDICAL CARE

The Board of Trustees, following a meeting of its Executive Committee with the representatives of the American Public Health Association in December 1937, passed resolutions which called for a determination of the need for medical services and, based on these findings, suggestions of preferable procedures to meet the need of persons in every county in the United States. This project is but a furtherance and extension of the encouragement which the Association has previously given to

state and county medical societies to develop means by which all persons might readily obtain medical care at fees commensurate with their ability to pay. Already, 250 or more county medical societies have endeavored to meet their local needs by some arrangement to make medical service more readily available to the indigent and low income groups. Many of these medical society arrangements have been in operation a sufficient length of time to permit some evaluation of their desirable and undesirable features. Of considerable significance is the fact that each locality apparently requires a different arrangement to organize or coordinate its medical services.

This new project calls for concerted action on the part of medical societies to determine medical needs by seeking the assistance of individuals, agencies and organizations that have an interest in or are actually endeavoring to supply medical care. If thoroughly and conscientiously carried out, such a project should give much needed dependable information. When the county medical societies, in cooperation with the other agencies and organizations concerned with medical services, shall have collected the data pertaining to need for medical services, it will then be possible to recommend preferable procedures intended to meet that need. It is logical and desirable for the county medical society to serve, with the guidance of the state association, as the coordinating unit for whatever organizational arrangements may be devised. Many medical societies will probably desire some suggestions as to the methods that have shown the most promise of fulfilling needs in other communities. It is suggested that at least one of each type of the county medical society medical service plans now in operation should be carefully examined at once so that the American Medical Association will be in a position to give the latest and most complete data concerning organization arrangements for medical services to those county medical societies that request assistance.

There can be no question that this project gives promise of a thoroughgoing analysis of the adequacy or inadequacy of the present distribution of medical services and is a significant opportunity for medicine to devise efficient and ethical means to distribute medical services to all people on the basis of need rather than to small groups within the population according to political expediency or special interests. With real and sincere cooperation from individuals, agencies and organizations concerned with medical services in each community, the success of the project will be assured.

NEW FORMS OF MEDICAL CARE

Within the past year a great many plans for organizing medical services have been proposed or actually inaugurated. Most of these plans are conceived with the idea of offering "low cost" medical services to special groups of persons. Industrial medical care plans are offered for employees of a single company, cooperative or group health associations for groups of employees and their dependents, student health services for students, lodge plans for members of fraternal orders and resettlement medical care plans for clients of the Farm Security Administration, and other types of group payment or insurance plans are held out as essential to provide medical services for particular groups of persons.

It is possible to organize medical services either geographically or by some special grouping of persons. The use of the two methods of organization at the same time creates overlapping and duplication. The development of numerous small administrative units for the provision of medical services to groups of persons selected on some basis such as occupation or social interests is of very questionable wisdom. The geographic method of medical practice, by which all the residents in a community obtain their medical care directly from the physicians in that community, has proved its superiority over any other method yet devised. Under this method of distributing medical services, the patient is considered in the perspective of a human being subject to his entire environment rather than as a member of some restricted or cultural group. The particular interests of special groups of individuals in the community, such as employees, students, the indigent and the low income group, can be met by slight adjustments in the existing method of providing medical services and without necessitating a special administrative organization.

The reason prompting the development of isolated plans for medical care is the notion that some organizational arrangement will result in low cost services. A number of fairly reliable surveys have shown that medical services cost, on the average, about \$25 to \$30 per person annually. It is hardly possible that any organizational arrangement can lower this average cost except by excluding many services or by offering medical services of inferior quality. As a general rule, such plans do not offer the complete services claimed but exclude many expensive services and depend on special charges for necessary finances.

CONTRACT AND CORPORATION PRACTICE

Most of the plans offered under this head are nothing more than contract practice arrangements whereby physicians are induced to sell their services to a promoter, who in turn sells the services to prospective patients. The introduction of a third party in the provision of medical services transfers control over the quality of medical services to that third party. In most instances this third party is a corporation or association not amenable to examination of its ability to provide a good quality of medical care and responsible only to the extent of cash resources. The quality of medical services cannot be maintained if individual physician responsibility, assured by high standards of medical education and licensure and sustained by professionally ethical regulations of societies of physicians, is replaced with the limited nonmedical and usually nonethical responsibility of corporations and associations. Such agencies give no assurance that they will foster a medical service equal to that now given by duly qualified physicians in private practice.

It is unnecessary to disrupt the professional practice of medicine into a series of commercial institutional enterprises. Those who attempt to do so are too often motivated by false notions concerning the methods of distributing medical care, by unreliable or incomplete information concerning the lack of medical care, by a desire to make a place in the sun for themselves, or by selfish interests such as avoiding increases in wages and attempting to obtain better personnel relations.

Sufficient information has been accumulated on practically every scheme for organizing medical services to substantiate the claim that medical services of the same quality cannot be provided at any less cost by these schemes than in private medical practice. Likewise, there is no group of persons in a community which cannot obtain sufficient medical care by permitting each person the freedom to choose his own physician. Progressive developments in workmen's compensation, industrial medical care plans and student health services indicate that a plan solely for the payment of medical bills (without control of the services) which permits free choice of physician and free choice of hospital is not more expensive and does not interfere with the quality of medical services or with the private practice of medicine. Furthermore, such arrangements have the full cooperation of medical societies. Plans that depend on underbidding, advertising, solicitation and other practices which impair the quality of medical services or prevent the development of an improved service can never be justified. Poor medical care, even if it is cheap and plentiful, may be worse than no medical care at all. Medical cults, quacks and "patent medicines" make a certain type of service more readily available at low cost, but these services have been strongly denounced.

Collecting the average annual cost for medical services from each of a number of persons in the hope of relieving a few individuals from possible large medical bills—the insurance principle—is another feature of group payment plans which is so plausible in appearance that many persons have not taken pains to examine the practical effects of such an arrangement. First of all, a considerable charge must be added to the average cost for each person to provide for the administrative expenses of any insurance plan. Next is the impossibility of calculating in advance a premium that will provide for the costs of new developments in medical science. The result is an inevitable collision between the resources of the insurance system and the needs of the insured persons for new and indeterminate amounts of expensive medical services. Another difficulty is that each individual who pays into the insurance

fund will make a conscious effort to obtain as much medical service as possible even if he does not actually need medical care. The medical profession has never objected to the insurance principle as a method of providing cash payments to individuals for medical and hospital bills such as the health and accident insurance policies which have been issued by insurance companies for almost a hundred years. The medical profession does object to the attempt of any corporation or association to provide, control or manipulate the actual medical services. Reputable insurance companies have found that it is undesirable both in the interests of their policyholders and for financial reasons to attempt to provide actual medical services through contract physicians or hospitals. It is hoped that the public and those who have been misled by the promises of certain new forms of medical care will finally realize that any plan which destroys professional control over the quality of medical services will only result in a low grade medical service which in itself may have as many potentialities for danger to health and life as the illness from which the individual seeks relief.

GROUP HEALTH ASSOCIATION, INC

Another development in methods of distributing medical service is found in a certificate of incorporation filed in the office of the Recorder of Deeds of the District of Columbia, Feb 24, 1937, on behalf of Group Health Association, Inc. The certificate makes eligible for membership every employee of every branch of the United States government other than officers and enlisted men of the Army and Navy. It attempts to authorize the association

To provide without profit to the corporation for the service of physicians and other medical attention and any and all kinds of medical surgical and hospital treatment to the members hereof and their dependents and the construction and operation of a clinic and medical office building and the construction and operation of a hospital in the manner permitted by law for the members hereof and their dependents and the operation of a drug store or pharmacy and the providing of nurses and of drugs and remedies for the members hereof and their dependents and the furnishing of all forms of hospital service and attention to the members hereof and their dependents and in general the giving to the membership of this association and their dependents of all forms of care treatment or attention that may be required by the sick or in the prevention of disease.

In the report from the Committee on Appropriations (to accompany H. R. 8837) the following statement appears:

Entirely irrespective of the merits of the work proposed to be done under the Group Health Association for which the Home Owners Loan Corporation recently made a contribution of \$40,000, the committee is of the unanimous opinion that the expenditure was one not authorized by law and that such expenditures should not hereafter be made without specific legal authority.

According to newspaper reports, the Federal Home Loan Bank Board guaranteed an advance up to \$100,000 to get the association under way.

In order, however, that the corporation might supervise and direct the activities of the association, the Home Owners' Loan Corporation insisted that it be given authority to name two of the trustees of the Group Health Association.

The form of application for membership provided by Group Health Association was arranged to give the member the option of paying his dues personally or of assigning to the association so much of his government salary as may be necessary for that purpose and requesting his "employer," the government of the United States, to deduct semi-monthly the amount assigned and remit it to Group Health Association, Inc. As this assignment form is also an application for membership and obviously belongs to the files of the association, an additional assignment form has been provided presumably to be filed with the paymaster of the Federal Home Loan Bank Board or the particular affiliate of the board by which the member of the association is employed. This form specifically assigns, sets over and directs the Home Owners Loan Corporation and the Federal Savings and Loan Insurance Corporation to pay Group Health Association the amount due to that association, out of any salary or wages due or to become due to the member so long as membership continues.

The United States district attorney for the District of Columbia has held that the association is engaged unlawfully in the practice of medicine and the insurance commissioner has

held that it is engaged unlawfully in carrying on the business of insurance. The status of the association with respect to these matters is at present writing before the courts for determination. Although the activities of Group Health Association, Inc., have thus far been limited to the District of Columbia and adjacent areas in Maryland and Virginia, the articles of incorporation in no way limit the area in which it may function. Membership in the first instance was restricted to officers and employees of the Home Owners' Loan Corporation and its affiliates, but more recently members have been accepted from other branches of the government.

So far as is known this is the first time that any governmental agency, federal or state, has undertaken through the use of public funds to subsidize a private lay corporation to provide medical services in competition with legitimate practitioners of medicine. Although in the present instance the granting of this subsidy has been held to be without authority of law, there seems to be no way which the taxpayers in the country can recover their misapplied money.

GROUP HOSPITALIZATION

Beginning in 1933, several publications of the Bureau of Medical Economics dealing with group hospitalization plans have emphasized that medical services should not be included in hospital service contracts. In the 1935 Annual Report of the Bureau, it was stated:

The medical profession is opposed to any plan that will destroy the basic features of medical service or will permit hospitals to enter the practice of medicine. If hospitals are permitted to include medical care in their contracts for hospital service the precedent is set for institutionalized contract medical practice with all its destructive effects on the art and science of medicine.

The report of the Judicial Council for the same year also stated:

Whether the scheme [meaning the group hospitalization] is or is not financially or economically sound is not the problem of our organization but it is our business to see that the furnishing of medical service is not included in the sale of insured hospital accommodations. This can be done if a strong stand is taken and maintained by the organized medical profession, which must keep a watchful eye to see that medical care is not initially or later included when the usual sales efforts demand increased benefits to purchasers.

At the annual meeting of the House of Delegates in Kansas City, May 11-15, 1936, three resolutions were presented that dealt with group hospitalization plans and medical practice in hospitals. The first of these, presented by the Section on Radiology, condemned the attempts of lay groups to provide diagnostic medical services along with and as a part of hospital services and resolved that the Council on Medical Education and Hospitals be authorized to take steps that would result in the practice of medicine being conducted by physicians and not by hospitals. The second resolution from California, also denounced the attempt of organized lay groups to provide diagnostic medical services as a part of hospital services and disapproved of the division of any branch of medicine into technical and professional portions. The third resolution, from Pennsylvania, insisted that the practice of radiology is the practice of medicine and disapproved of the proposal of certain hospitals to divide the practice of radiology into professional and technical services.

These three resolutions were consolidated in the following report of the Reference Committee:

It reiterates the principle enunciated by the House of Delegates at Cleveland in 1934. That the practice of radiology whether for diagnostic or therapeutic purposes constitutes in fact the practice of medicine. The action of the House of Delegates in 1925 establishing a section on radiology confirms this principle.

It further recommends that all services connected with the practice of radiology be under the direct control and supervision of the medical profession and this same principle pertains to other technical and professional services.

This report was adopted by the House of Delegates.

Again in the 1936 annual report of the Bureau it was necessary to report that "few, if any, of the plans exclude all medical services from their group hospitalization contracts" and that "these prepayment plans for hospital care show a distinct tendency to place hospitals themselves in the field of medical prac-

tice." Based on a complete study of group hospitalization plans, ten principles were suggested, the fourth of which was as follows:

The subscriber's contract should exclude all medical services—except those provisions should be limited exclusively to hospital facilities. If the service is limited to include only hospital room accommodations, bed and board, operating room medicines, surgical dressings and general nursing care the distinction between hospital service and medical service will be clear.

This and the other principles were adopted by the House of Delegates in Atlantic City in 1937 as follows:

That portion of the report of the Board of Trustees devoted to the Bureau of Medical Economics goes into careful detailed consideration of the question of group hospitalization. Your reference committee recommends the principles stated in that section of the report pertaining to group hospitalization and recommends the adoption of those principles as the policy of the American Medical Association, and it is urged that the medical societies in those communities in which group hospital insurance is thought to be necessary be guided by these principles to the end that such schemes confine their contract benefits strictly to the facilities ordinarily provided by hospitals, viz hospital room, bed, board, nursing, routine drugs. It is suggested that the Bureau of Medical Economics continue to collect factual and statistical data concerning group hospital insurance experience and make these facts available from time to time.

In reply to a resolution from Ohio (1937) asking for a clarification of the policy of the American Medical Association with regard to what medical services should not be included in a group hospitalization contract, the reference committee reported as follows:

It is recommended therefore, that the contract benefit provided by group hospitalization insurance should be limited to the room, bed, board, nursing facilities ordinarily provided by hospitals and routine medicines.

Your reference committee would refer to principle 4 (as already given) which was adopted by this House of Delegates. In that paragraph the limitations of hospital service are well defined. Your reference committee reaffirms this definition of hospital care and recommends its application to contracts for group hospitalization. In regard to certain benefits offered by many hospital insurance plans combining professional and technical services your reference committee is in complete sympathy with those who would make every possible provision to prevent inclusion of any and all types of service involving medical care.

This report was adopted.

Shortly after the 1937 action of the House of Delegates was made public, editorials appeared in hospital magazines which seem to indicate a complete disregard on the part of certain hospital groups for the desires and recommendations of the medical profession as expressed by the House of Delegates. Excerpts from these editorials are as follows:

Ten years hence what will the verdict of history be on the action of the House of Delegates of the American Medical Association last June when it attempted to set up a barrier between medical and hospital services and laid down the law to group hospitalization plans?

Is it the prerogative of the medical profession to decide on hospital policies all by itself? As a practical matter well organized group hospitalization plans that have already included x-ray, anesthesia and laboratory services with the cooperation of their local medical societies are likely to go ahead as they have been going.

No one is justified so far as the patient is concerned in taking the hard-boiled attitude that hospital care has any limitations as far as the welfare of the patient is concerned. Whether he is a charity patient or one who pays in part or in full for his care, he is entitled to every attention in consonance with the established standards which the medical profession and the hospitals unite in maintaining. The patient, whatever his economic status is entitled to receive the necessary service of the clinician, the surgeon, the pathologist, the radiologist, the nurse and the lay people who attend him. All these services are a part of the hospital coordinated by the hospital for the benefit of the patient. Hospital must provide this service. They cannot accept the dicta of a minority of medical men who place their own financial advantage above the welfare of the patients under their care.

At the Atlantic City Convention of the American Medical Association last June resolutions were adopted calling on group hospitalization plans to furnish hospital care only and specifically to exclude laboratory service, x-ray and anesthesia. Are several hundred hospitals, several thousand trustees and several hundred thousand citizens who are members of these plans to be under dictation from a national association of staff physicians of local medical societies? The good sense of staff physicians of local medical societies and hospital trustees and administrators will prevent this being the case.

In several other respects studied attempts have been made to discredit the recommendations of the House of Delegates that medical services be excluded from hospital service contracts.

In verification of the fact that the House of Delegates of the American Medical Association is truly representative of

the majority of physicians in the United States—if such verification is needed—state medical societies in twenty-one states have passed resolutions or adopted reports of committees recommending that medical services be excluded from hospital service contracts, whereas in only one state can the medical society be considered as approving of the inclusion of medical services in group hospitalization contracts, and this only by inference because the society has endorsed a group hospitalization contract which includes medical services. In the remaining states this problem has not arisen or no definite official action has been taken, but the attitudes expressed and the resolutions adopted on similar problems indicate that the inclusion of medical services in a hospital service contract is not looked on with favor. Many county medical societies have also taken action against the inclusion of medical services in group hospitalization contracts. It can be accepted that the conviction of the medical profession throughout the United States is that medical services should not be included in hospital service contracts.

In chapter IV of the study "Group Hospitalization" is a full discussion of the attitudes toward the inclusion of medical services in group hospitalization contracts taken by societies of radiologists, pathologists and anesthetists, as well as by associations of hospitals. The effect that the inclusion of special medical services such as anesthesia, pathology and radiology in a hospital service contract will have on the practice of these medical specialties is also discussed in this study. Three thousand copies of the study have been distributed by request to hospital administrators, physicians and lay persons.

Two proposals were suggested in the study to avoid the difficulties created when hospital services are sold in a contract. The first is to restrict the benefits of the hospital insurance contract exclusively to hospital facilities such as bed and board, operating room, medicines, surgical dressings, and general nursing care. The second proposal is that all benefits should be paid in cash to the subscriber, who could then purchase his hospital service without disturbing or altering the relations between physicians and hospitals. The best arrangement for a hospital service contract depends on the many factors involved in the particular locality, but it is clear that no form of medical service should be included in such contracts. There are several indications that the special medical services in contracts now sold by group hospitalization plans may be removed from new contracts and from the renewal of existing contracts.

Nevertheless, proponents of group hospitalization plans have insisted that certain anesthesia, pathologic and radiologic services can be included because the hospital reimburses anesthetists, pathologists and radiologists in accordance with previously existing financial arrangements. They seek to interpret the principle that medical services should not be sold in a hospital service contract as a prohibition against hospitals providing anesthesia, pathologic and radiologic services for all patients as follows:

If the general principle as laid down by the House of Delegates is sound, what is the logic of applying it to group hospitalization only? And if it is to be applied to all anesthesia, x-ray and laboratory services for all patients, why then the hospitals are in for a considerable revamping of their professional administrative and financial organizations that is they are in for a reorganization in so far as they decide to reorganize.

This larger problem of the relations between hospitals and physicians concerning the practice of medical specialties in hospitals and, in particular, the method of remuneration for such medical specialties has already been given considerable attention by the House of Delegates and is now the subject of an investigation by the Bureau of Medical Economics. This problem, however, should not be allowed to confuse the principle which has been established concerning group hospitalization contracts, namely, that medical services should not be included in such contracts.

EXPANSION OF HOSPITAL FUNCTIONS

Since the beginning of the twentieth century there have been tremendous changes in the traditional function of hospitals. Hospitals have always been regarded as specially equipped institutions for the hospitalization of patients who could not be treated satisfactorily in their homes or in the physicians'

offices. Now hospitals are beginning to assume a dominant place in the practice of medicine and in the delivery of medical care to the American people. In this newer role hospitals have, unfortunately, been assisted or encouraged by some members of the medical profession. The importance of the individual physician as the primary figure in medical care is obscured by a trend toward institutionalized medicine with the hospital as the central figure.

The first step in this direction was made when hospitals began the operation of pay clinics and outpatient departments. The original concept that outpatient services and part-pay clinics should be maintained only in teaching institutions where patients were needed for clinical material or only for indigent patients was soon forgotten and outpatient departments and clinics were developed with little regard for the disturbances they caused in the practice of private physicians. Further steps toward the practice of medicine by institutions were taken when hospitals adopted "all-inclusive rate" plans such as the "middle rate" plan, whereby patients are admitted on an adjusted fee basis including medical care as well as the use of hospital facilities, or the "flat-rate" plan, under which patients are admitted for diagnostic services and pay a flat fee covering the complete cost of all diagnostic medical services and use of the hospital facilities. The latest step has been the sale of group hospitalization contracts which offer purchasers the services of medical specialists as well as the use of the physical facilities of the hospital.

MECHANICAL AIDS IN MEDICAL PRACTICE

Other factors have been responsible for or have encouraged these changes. Perhaps the main factor is the widespread belief that machinery is revolutionizing the practice of medicine and is dispensing with the need for human judgment. The introduction of instruments for more precise diagnosis such as the x-rays, the electrocardiograph, metabolism testers, and other mechanical devices for laboratory tests, has led many persons to believe that exact diagnosis can be given without depending on the knowledge, experience and judgment of a physician. As a consequence, the accumulation of new and expensive equipment in hospitals is apparently thought by many to be more essential to good medical service than the personal ministrations of physicians.

A corollary of the tendency to emphasize mechanical devices is the attempt to standardize medical procedures and to provide them on a low cost, mass production scale. Such attempts are based on the belief that a human being can be regarded as a uniform, standardized organism. This is a fundamental fallacy, as no two individuals react in the same way to the same disorder. When an institution concerned with medical services tries to assume or actually adopts any of the characteristics peculiar to a great industry such as advertising, large capital investment or mass production, a deterioration in the medical services results. There is no way to standardize the infinite variety of human beings in health and disease.

As a consequence of the changes in the function of hospitals, medical practice in hospitals has now reached a stage somewhat analogous to the condition of medical education in 1904. To improve the then existing situation in medical education, the American Medical Association established an ideal standard of medical education and gained world renown through the council on Medical Education and Hospitals for raising medical education toward that standard. Existing practices or prevailing policies of medical education were not accepted as controlling, instead an ideal standard that would foster an ever improving quality of medical education was adhered to. This ideal standard has not yet been fully attained but no one can deny its value in improving the quality of medical services in the United States.

PRESENT TENDENCIES TOWARD THE PRACTICE OF MEDICINE BY HOSPITALS

The present situation in the practice of anesthesia, pathology and radiology in hospitals and the potentiality of increasing the number and variety of special medical services controlled by hospitals call for the establishment of a similar ideal standard designed to permit a constant improvement of practice in hospitals.

The action of the House of Delegates in 1904 was directed against the practice of medicine by incompletely trained physicians, cultists, quacks and lay persons. Today action must be directed against the attempt of corporations and associations to practice medicine by employing nurses and technicians under the tacit supervision of salaried physicians. The years of work that have been spent in raising the standards of medical education will be nullified if lay persons, nurses and technicians on the pay roll of a corporation or association are now permitted to give medical services.

To offer a lower cost service, hospital administrators and even some physicians have delegated many anesthesia, radiologic and pathologic duties to nurses and technicians. Such a utilization of nonmedical personnel may be permissible provided the quality of the medical service is not adulterated. It is false economy to place a portion of the practice of medicine in the hands of incompletely trained persons if the quality of the service is cheapened or if the development of an improved service is retarded. The service offered by the indiscriminate use of nonmedical personnel may cost less, but it will be of less value in preventing or overcoming disease, and, what is more important, there will be no encouragement for medical students to train themselves for such services if these fields are being filled or usurped by medically untrained persons receiving small incomes. The opportunities for physicians to establish desirable practices in these fields are becoming so limited that they turn to other types of practice. The result is an underdevelopment of the scientific possibilities of the practice of anesthesia and pathology. The line between the functions which may be performed by nonmedical persons and the functions which can properly be performed only by a physician may be difficult to draw. It may be reasonable to believe that the utilization of nonmedical persons only under the direct and immediate supervision of qualified physician-specialists will permit lower costs without endangering the quality of the service or retarding the improvement of the practice of medical specialties in hospitals.

The problem to be faced is: Shall more and lower-cost special medical services in hospitals be performed by persons less highly trained than physicians, or shall the quality of medical services be maintained by insisting that medical services be performed only by or under the immediate direction of properly trained physicians? Undoubtedly, the latter is more desirable. Entirely apart from the legal aspect of the question, there is not sufficient evidence that the people of the United States are unable to buy adequate medical services of a quality offered by competent physicians to warrant an adulteration of medical services by permitting corporations, nurses, technicians or lay persons to practice medicine.

Whatever antagonism has developed between hospitals and physicians over group hospitalization plans is but an outgrowth of already existing unsatisfactory relations between hospitals and physicians. The pressure that has been placed on hospital administrators to find some source of income to finance their large capital investments and to continue to provide extensive free services has led many hospital administrators to adopt policies deleterious to the entire practice of medicine. Some of these are solicitation of patients, advertising, the entrenchment of nurse anesthetists, the placing of more and more of the practice of radiology in the hands of incompletely trained lay technicians, and the forcing of pathology from its rightful position in the practice of clinical medicine.

All these policies are undertaken for the essential purpose of increasing hospital revenue to permit the continuation of the services rendered to the residents of the community. Sympathy must be expressed for the financial difficulties faced by hospitals, and all just means of financial assistance should be encouraged. Nevertheless, the improvement of hospital finances must not be at the expense of the quality or the opportunities of medical practice.

It is unethical, and therefore contrary to good public policy, for hospitals to participate in the practice of medicine in order to obtain an income to finance other hospital activities or to attempt to lower the cost of special medical services by methods that impair the quality of the service or prevent the development of an improved service. Where such a situation

exists the patients may be overcharged for the medical service of the medical department, the medical specialists may be receiving an insufficient income, or the services may not be maintained at a proper standard because of the use of cheap technical assistants or because of inadequate equipment, or insufficient or underpaid personnel. The proper method of remuneration for the hospital and the physician should enable the hospital to provide adequate building, equipment and personnel without necessitating an attempt to control or to employ physicians and should permit the physician to schedule his charges so as to make it possible for all patients to have easy access to necessary special medical services. In keeping with the ethics of the medical profession, both hospitals and physicians must place service first and financial considerations second.

QUALITY OF MEDICAL CARE MUST BE MAINTAINED

The present high plane of medical practice is largely the result of constant supervision of the practice of medicine by organized societies of physicians. It does not appear that any other organization is so capable of developing the practice of medicine to an increasingly higher plane of service. The public, as well as all the agencies in the medical field, look to the medical profession for improvements in the practice of medicine. A resolution by a national hospital association concluded that

the medical profession must be accorded predominant influence in the medical activities of all institutions giving health and sickness care and, therefore, the hospital members of this association commit themselves to the policy that the rights, duties and privileges of the medical profession be considered directive and authoritative in hospital science and service.

The turmoil between hospitals or agencies representing hospitals and national societies of anesthetists, of pathologists and of radiologists cannot continue without harmful effects on the practice of medicine in hospitals. It is of utmost importance for the House of Delegates to outline the steps that will lead those interests now in conflict to a common ground of understanding. The future course of the practice of medical specialties in hospitals will be largely dependent on the solution of the present difficulties in the relations between hospitals and physicians.

WORKMEN'S COMPENSATION

The period since 1930 has been one of exceptional developments in workmen's compensation legislation. Improvements in the relations with organized medicine in regard to medical care are particularly noticeable. The trend which has existed since the beginning of workmen's compensation legislation in the direction of increasing the amount of medical services to injured workers has proceeded at an accelerated rate. The inclusion of occupational diseases is especially significant, since 1930, fourteen states have included or increased the coverage for such diseases. A supplement to the publication "Medical Relations Under Workmen's Compensation," entitled "Developments in Workmen's Compensation since 1930," recounts these recent changes.

Even more significant, from the point of view of the medical profession, is the tendency to seek the direct cooperation of state medical societies in the administration of compensation laws. In New York State an act—significantly known as the "Medical Abuses Act"—has thrown the responsibility for determining the competence of physicians admitted to care for compensation cases on the state and county medical societies. Each county society is required by law to prepare a panel of all those considered competent to care for such cases, and this panel, when approved by the compensation officials, becomes a part of the administration machinery. Injured workers have free choice among all physicians approved by the county medical societies and placed on the panel. The law has been in operation a little over a year and has been approved by the supreme court.

Similar legislation is being considered in several other states. In some fourteen states the medical society is at least semiofficially recognized usually through a committee of the state medical society, as an organ of administration. In some states such a committee passes on all contested cases and its opinion is accepted as final. In others it is directed

consulted and its approval generally accepted in the formation of panels of physicians, among whom there is free choice. In numerous states committees of either state or county medical societies charged with the duty of adjusting medical bills have been approved by insurance carriers and administrators.

These developments are apparently approaching a solution of some of the problems that have given rise to the sharpest conflict between the medical profession and compensation carriers and administrators. Freedom of choice is now being granted workers from lists of physicians whose competence is vouched for by organized medicine. The question of the fairness of medical bills is being left to the decision of committees of state and county medical societies. Whereas a previous study showed that in many states such conflicts led to undesirable friction and difficulties, information from both administrators and state medical societies now uniformly indicates that such difficulties are being adjusted and both sides speak frequently of the excellent relations now existing.

INSURANCE MEDICAL DIRECTORIES

At the annual meeting of the House of Delegates of the American Medical Association in 1936, a resolution was adopted condemning the listing of a physician's name for a fee in a directory which indicates his specialty and his availability for insurance and compensation work and for other professional services. At the time of the adoption of this resolution, at least fourteen concerns were publishing such insurance medical directories and were soliciting physicians for a listing of their names on the payment of a \$10 to \$75 fee. In January 1937 an article published in the Organization Section of *THE JOURNAL* called attention of physicians to the resolution, to the sales devices used by the publishers of insurance medical directories and to the inadvisability of paying a fee for a listing in such directories.

Despite the fact that the listing of a physician's name in an insurance medical directory was condemned as an unethical, indirect solicitation of patients, and despite the fact that such directories mainly serve the profits of the publishers and are of little benefit to physicians and insurance companies, many physicians continued to support medical directories. In September 1937 a second article published in the Organization Section of *THE JOURNAL* gave the results of a survey of 220 insurance companies in the United States and Canada—representing all types and sizes of companies. This survey showed conclusively that insurance medical directories are not used in the selection of insurance examiners. The directors of medical departments of insurance companies have found that there is no real selection of physicians in such commercial directories and for that reason they employ independent methods to determine the qualifications of physicians as insurance medical examiners. Most insurance company officials have learned that the physician who subscribes to these commercial lists may have no particular qualifications for insurance service other than his willingness to have patients referred to him and his desire to collect a fee.

Several of the publishing concerns have now discontinued their insurance medical directories and others are considerably less active. In one locality physicians caused the arrest of a salesman for an insurance medical directory on the grounds of his obtaining money through misrepresentation. Bona fide directories of physicians, published by the American Medical Association, by state and county medical societies and by well established organizations do not ask any entrance fee from the physicians listed therein. These directories adequately fill the needs of insurance companies for lists of physicians, by locality and type of practice, to supplement the regular procedure followed in the selection of insurance medical examiners.

A considerable number of requests are still received from physicians concerning the desirability of paying a fee for a listing in a directory purported to be used for selecting insurance medical examiners. It is hoped that the information contained in the two articles which appeared in *THE JOURNAL* and are available in reprint form entitled 'Medical Directories' will be widely utilized to prevent physicians from being victimized by publishers of pay-as-you-enter insurance medical directories.

OTHER ACTIVITIES

As measured by the volume of correspondence received during the year, physicians, lay persons and administrators of various agencies showed the greatest concern over group hospitalization plans, insurance companies (particularly malpractice insurance), contract practice plans, socialized medicine and workmen's compensation in the order mentioned. It is significant to notice an apparent subsidence of concern over health insurance as indicated by the Bureau of Correspondence.

State and county medical societies were especially interested in obtaining complete information about group hospitalization plans in operation and analyses of proposed plans. Medical societies also desired information concerning the method of organization and operation of professionally controlled credit and collection bureaus. The information that has been collected from such bureaus will be made available in the Organization Section of *THE JOURNAL*. There is some indication that medical societies are now taking more interest in student health services. Many copies of the report 'University and College Student Health Services' were distributed to state and county medical societies.

Many articles and abstracts pertaining to current medical economic problems were prepared for the Organization Section of *THE JOURNAL*.

Representatives of the Bureau traveled to twenty-two states for speaking engagements or conferences in the interests of state and county medical societies. The Bureau also cooperated with the Bureau of Exhibits in the preparation of material to be exhibited at meetings of state and county medical societies and of other groups such as the American College of Surgeons.

Summary

Survey of Need for Medical Care—Within recent years there has been considerable agitation for socialization of medicine by some grandiose system of organizing, distributing and controlling medical services. As a result, many persons have been misled into the belief that medical services in the United States are grossly inadequate despite the fact that in many health and medical surveys only about 10 per cent of the population have been shown to be in need of medical care which they presumably desire but are not receiving, that 90 per cent of all sick persons are attended by physicians, and that the morbidity and mortality rates rank the United States as one of the most healthful countries in the world.

Consistent with the interest which the American Medical Association has always maintained in health and medical matters, the Board of Trustees of the American Medical Association passed resolutions calling for the determination of the actual needs for medical services in every county in the United States. All county medical societies, in cooperation with other agencies and organizations concerned with medical services, will be encouraged to collect data pertaining to need for medical care and to recommend preferable procedures to meet that need. This project is but a furtherance and extension of the encouragement which the Association has previously given to state and county medical societies to develop means by which all persons might readily obtain medical care at fees commensurate with their ability to pay.

New Forms of Medical Practice—A large number of plans have been proposed or actually inaugurated for the purpose of offering "low-cost" medical service to some special groups of persons. The creation of special administrative organizations for every social, industrial and cultural group will necessarily mean a maze of small administrative units. The desirability of such a method of distributing medical services is extremely doubtful from the point of view both of economy and of good medical practice.

Sufficient evidence has been accumulated on practically every scheme for organizing medical services to disprove the claim that some organizational arrangement can

lower the cost of good medical services. Certainly no system of collecting payments for medical care can lower the average cost of \$25 to \$30 per person annually unless many essential services are excluded or medical services of less than average quality are offered. Plans that depend on underbidding, advertising, solicitation or similar practices to provide cheaper services impair the quality of medical service and prevent the development of an improved service.

Group Hospitalization—The House of Delegates of the American Medical Association, state and county medical societies, and national societies of specialists have all recommended that medical services be excluded from group hospitalization contracts. The medical profession is convinced that the inclusion of medical services "in kind" in group hospitalization contracts will have an undesirable effect on the practice of medical specialties in hospitals, and therefore on the quality of the services rendered. Two proposals have been suggested as a solution to the problem of medical services in group hospitalization contracts: (1) restrict the benefits of the contract exclusively to the use of hospital facilities such as bed and board, operating room, medicines, surgical dressings and general nursing care, and (2) pay cash benefits directly to the insured for all medical services. Several group hospitalization plans now exclude medical services or offer cash benefits for such services, and the indications are that other plans will do likewise.

There is need for the House of Delegates to adopt a standard for medical practice in hospitals which will permit the constant improvement of medical services. The years of work spent in raising the standards of medical education will be nullified if hospital corporations and associations are permitted to sell medical services to patients by employing lay persons, nurses and technicians to render certain medical services under the tacit supervision of salaried physicians.

Workmen's Compensation—Since 1930 there have been several exceptional developments in workmen's compensation. Outstanding is the tendency to seek the direct cooperation of medical societies in the administration of workmen's compensation laws. In an increasing number of states, injured workmen are now being allowed freedom of choice of physician from lists of physicians vouched for by medical societies. A report entitled "The Developments in Workmen's Compensation since 1930," which recounts these changes, is now appearing in the Organization Section of The Journal.

Insurance Medical Directories—A considerable number of requests are still being received from physicians concerning the desirability of paying a fee for a listing in a directory purported to be used for selecting insurance medical examiners. In 1936 the House of Delegates adopted a resolution condemning the listing of a physician's name for a fee in a directory which indicates his specialty and his availability for insurance and compensation work and for other professional services. The information contained in the pamphlet "Medical Directories," if utilized, should prevent physicians from being victimized by publishers of pay-as-you-enter insurance medical directories.

Other Activities—As measured by the volume of correspondence, the most interest was shown in group hospitalization plans, insurance companies, contract practice plans, socialized medicine and workmen's compensation. A noticeable subsidence of concern over health insurance occurred.

Many articles and abstracts pertaining to current medical economic problems were prepared for the Organization Section of The Journal. Representatives of the Bureau attended meetings in twenty-two states for speaking engagements and conferences or to exhibit medical economic material.

Bureau of Investigation

While the larger part of the work of the Bureau of Investigation is conducted through correspondence involving receipt and answering of from ten to twelve thousand communications a year, the Bureau of Investigation has continued its cooperation with medical societies and other professional groups, with teachers, with health departments and with other organizations interested in sound medical practice and in health education.

Exhibit material has been supplied on request. Each year the number of inquiries received from laymen shows a distinct increase, most largely accounted for by requests received from students whose teachers and textbook references direct them to the Bureau of Investigation of the American Medical Association for information.

The publishers of newspapers and magazines and the operators of radio broadcasting stations and of advertising agencies continue to call on the Bureau for information regarding advertising, and charitable and educational institutions and rating agencies frequently avail themselves of the services of the Bureau. The utmost cooperation has been offered to various agencies of the federal government, including the Post Office Department, the Food and Drug Administration, the Federal Trade Commission and the Federal Bureau of Investigation as well as Better Business Bureaus and official departments of municipalities. All these agencies have reciprocated in replying to inquiries addressed to them by the Bureau of Investigation.

Dr. Frank J. Clancy, who succeeded Dr. Arthur J. Cramp as director of the Bureau, resigned Oct. 1, 1937, in order to return to the private practice of medicine. During the year, and prior to his retirement as director, Dr. Clancy appeared before twenty audiences in widely separated parts of the country for the purpose of discussing important subjects of popular interest with which the work of the Bureau is directly concerned. During the year, twenty major articles dealing with as many subjects were prepared by the Bureau and published in The Journal.

The demand for pamphlets and leaflets pertaining to frauds in medicine and to quackery was fully sustained during the year. Some of the older pamphlets issued by the Bureau were revised and new ones were added to the list available for distribution.

Summary

The work of the Bureau of Investigation has been continued along the usual lines. From ten to twelve thousand direct communications are answered by the Bureau each year. There is a constant increase in the number of inquiries received from laymen. The Bureau has continued its cooperation with medical societies and other professional groups and with various official agencies of federal, state and city governments. An increasing number of inquiries come from students in universities, colleges and schools. The director of the Bureau actively participated during the year in the field work of the Association. The usual demand for the pamphlets of the Bureau has been fully sustained.

Bureau of Exhibits

The report of the Bureau of Exhibits is presented under the following headings:

- The Scientific Exhibit
- Association Exhibits
- Exposition Exhibits
- Motion Pictures

The work of the Bureau of Exhibits involves cooperation with numerous agencies. The Scientific Exhibit is conducted with the advice of the committees of the fifteen sections of the Scientific Assembly and requires much correspondence with the committees and with the secretaries of the sections. Association exhibits present the work of the various committees and bureaus of the headquarters group and activities in connection require frequent consultations with the committees and bureaus. Requests for exhibits from lay organizations and

presented through county or state medical societies, thus furnishing frequent contacts with those societies. The able assistance of all these groups has contributed greatly to the success of the work of the Bureau and appreciation is hereby expressed.

THE SCIENTIFIC EXHIBIT

The Scientific Exhibit at the 1937 session was the largest in the history of the Association. The floor space in that part of the auditorium which was assigned to exhibits was crowded to capacity, requiring the use of the stage and of corridors on either side of the auditorium. One of the increasing problems of the Scientific Exhibit is to provide enough space to accommodate the crowds constantly in attendance. Approximately 50,000 square feet of floor space was required at the Atlantic City session.

Total Exhibits, 1937—There were 319 signed applications for space in the Scientific Exhibit at the Atlantic City session. Of these 249 were accepted and seventy rejected or withdrawn (29 per cent). The total number of exhibits shown was 254, divided as follows:

| | |
|-------------------------------|------------|
| Section exhibits | 194 |
| Symposium on heart disease | 25 |
| Educational group | 25 |
| A. M. A. headquarters group | 5 |
| Motion picture booths | 3 |
| Special (subsidized) exhibits | 2 |
| Total | 254 |

Although the number of exhibits in 1937 exceeded those of former years, the ratio for the attendance was almost exactly the same as in years past, 38.4 persons per exhibit.

Section Exhibits—The fifteen sections of the Scientific Assembly presented 194 exhibits, an average of thirteen each. The largest number shown was twenty-six, by the Section on Surgery, General and Abdominal, while the smallest number was eight, by the Section on Urology and the Section on Nervous and Mental Diseases.

Each section appointed a representative to assist in the matter of obtaining noteworthy exhibits in the various fields of medical endeavor. These representatives did excellent work, but some produced so much material that some embarrassment was created by lack of available space and facilities for handling.

Exhibits Presented by Sections of the Scientific Assembly

| | Atlantic City 1937 |
|--|-----------------------|
| Practice of Medicine | 18 |
| Surgery, General and Abdominal | 26 |
| Obstetrics, Gynecology and Abdominal Surgery | 10 |
| Ophthalmology | 11 |
| Laryngology, Otology and Rhinology | 9 |
| Pediatrics | 9 |
| Pharmacology and Therapeutics | 9 |
| Pathology and Physiology | 17 |
| Nervous and Mental Diseases | 8 |
| Dermatology and Syphilology | 12 |
| Preventive and Industrial Medicine and Public Health | 14 |
| Urology | 8 |
| Orthopedic Surgery | 11 |
| Gastro-Enterology and Proctology | 18 |
| Radiology | 14 |

The Section on Practice of Medicine was represented by Fred M. Smith, Iowa City. Twenty-seven applications were presented of which eighteen were accepted, one transferred to the Symposium on Heart Disease and two transferred to the Educational Classification. A certificate of merit and two "honorable mentions" were awarded to this section. Two papers were presented before the section by exhibitors. A special feature was the Symposium on Pneumonia consisting of three exhibits accompanied by lectures and motion pictures.

The Section on Surgery, General and Abdominal was represented by Lester R. Whitaker, Boston. There was a total of forty-three applications of which twenty-six were accepted, one transferred to the Heart Symposium and one to the Section on Preventive and Industrial Medicine and Public Health.

The section was given one certificate of merit and three "honorable mentions." Four papers were read by exhibitors on the same subjects as those carried by exhibits.

The Section on Obstetrics, Gynecology and Abdominal Surgery sent in fourteen applications, of which ten were accepted. There were two awards made to the section—a bronze medal and a certificate of merit. There were no papers presented by the exhibitors. In connection with the exhibits of this section there was conducted a motion picture program on carefully selected subjects, which drew large crowds. The section representative was H. Close Hesselstine, Chicago.

The Section on Ophthalmology had eleven applications for space, all of which were accepted and one of which was given "honorable mention." Six of the eleven exhibitors read papers in the section meetings. A motion picture program in conjunction with the exhibits was a special feature. Georgianna Dvorak-Theobald, Oak Park, was the section representative.

The Section on Laryngology, Otology and Rhinology was represented by Louis J. I. Burns, Philadelphia. There were seventeen applications presented, nine of which were accepted. One exhibitor read a paper.

The Section on Pediatrics, for which F. Thomas Mitchell, Memphis, Tenn., was the section representative, had eleven applications, of which nine were accepted. Three exhibitors read papers in the section meetings.

The Section on Pharmacology and Therapeutics presented ten applications, nine of which were accepted and one transferred to the Educational Classification. One exhibit received a silver medal. Four of the papers in the section meetings were presented by exhibitors. The section representative was Wallace M. Yater, Washington.

The Section on Pathology and Physiology was represented in the Scientific Exhibit by F. W. Konzelmann, Philadelphia. The number of applications for space totaled twenty-six, of which seventeen were accepted, three transferred to other sections and two transferred to the heart symposium. There were five awards—a gold medal, two certificates of merit and two "honorable mentions." Eight of the papers in the section meetings were from exhibitors.

The Section on Nervous and Mental Diseases presented eight applications, all of which were accepted. One exhibit received a silver medal and one special commendation. Three exhibitors read papers in the section meeting. The section representative was Peter Bassoe, Chicago.

The Section on Dermatology and Syphilology presented twelve exhibits from the fourteen applications for space. In the same group were shown two exhibits on syphilis from the educational classification. There was one "honorable mention" given. Three papers were read by exhibitors before the section. The section representative was Clark W. Finnerud, Chicago.

The Section on Preventive and Industrial Medicine and Public Health produced twenty applications, of which fourteen were accepted and one transferred. Three exhibits received "honorable mention." One exhibitor read a paper. Paul A. Davis, Akron, was section representative.

The Section on Urology, of which R. S. Ferguson, New York, was section representative, presented ten applications, with eight acceptances. One exhibit received a certificate of merit and one "honorable mention." Four papers in the section meeting were read by exhibitors. In the same group with the Section on Urology were shown two exhibits on gonorrhea from the educational classification.

The Section on Orthopedic Surgery presented eleven exhibits out of twenty applications for space. The awards consisted of a gold medal and a certificate of merit. Three exhibitors read papers in the section meeting. Three of the applications were for space to show motion pictures, which was done in an area adjoining the exhibits. Jesse T. Nicholson, Philadelphia, was the section representative.

The Section on Gastro-Enterology and Proctology had twenty-three applications for space of which eighteen were accepted. One certificate of merit was given. Four exhibitors read papers. The section representative was J. A. Borgen, Rochester, Minn.

The Section on Radiology, with E. E. Downs, Woodbury, N. J., as section representative, presented fifteen applications,

of which fourteen were accepted. There were several other applications presented by radiologists included in other groups, notably the heart symposium. Three exhibitors presented papers before the section.

Exhibit Symposiums—The exhibit symposium on heart disease was presented with the cooperation of the American Heart Association, with Thomas M. McMillan, Philadelphia, assisting. There were twenty-five exhibits covering different phases of the problems of heart disease, five of which received awards—a bronze medal, three certificates of merit and an "honorable mention." The exhibits were of exceedingly high caliber and aroused much favorable comment.

The exhibit symposium on pneumonia was presented under the auspices of the Section on Practice of Medicine. There were only three exhibits, but those three were well demonstrated and the booths were crowded most of the time. The motion pictures and the talks in an area adjoining the exhibits were somewhat disorganized by men not appearing to speak at the times advertised. The control of such activities by section exhibit committees is to be discouraged.

Motion Pictures—Three sections presented motion picture programs in connection with the exhibits—Obstetrics, Ophthalmology and Orthopedic Surgery. All the pictures shown were selected with considerable care by the section representatives, the pictures being previewed and parts cut out in some instances. The program was under the control of the Director of the Scientific Exhibit. The pictures on obstetrics attracted such crowds that the program had to be discontinued from time to time to allow men to reach the adjacent meeting hall. The pictures on ophthalmology attracted fair audiences, while those on orthopedic surgery were the least successful.

Many motion pictures were shown in the individual booths. There was some difficulty with bright overhead lights, requiring the erection of screens in some places.

Motion pictures still create a serious problem. A mediocre picture will sometimes attract attention beyond its intrinsic worth, while exceptionally good pictures will block the aisles and thus interfere with surrounding exhibits.

Special Exhibits—The Special Exhibit on Fractures was carried on under the efficient direction of Kellogg Speed, Chicago, assisted by Frank D. Dickson, Kansas City, and Walter Estell Lee, Philadelphia, with an advisory committee of fourteen and fifty-one demonstrators. The exact precision with which the demonstrations followed each other in all seven booths throughout the week bespoke of the careful planning by the committee in charge. The United States Army again assisted to the fullest extent, under difficult conditions. Surgeon General Reynolds made it possible for an officer and seven men from the Walter Reed Hospital to go to Atlantic City with a truck load of equipment. Major W. W. McCaw and the seven men were on continuous duty throughout the week. A booklet on fractures was in great demand.

A Special Exhibit on Anesthesia was put on for the first time and was not fully organized. R. M. Waters, Madison, Wis., with the aid of members of his own staff and other prominent anesthetists, conducted this exhibit. In spite of the loss in transit of part of the exhibit material and other difficulties, there was much interest in the exhibit, and the demonstrations, talks and motion pictures attracted good audiences. The pamphlet accompanying the exhibit was well received.

Committee on Awards—The Committee on Awards, composed of Ludwig Hektoen, chairman, A. J. Bedell, F. K. Boland, R. L. Haden and J. D. Trask, carefully studied all the exhibits over a period of three days and found the task of making awards extremely difficult, because of the large amount of material presented and its diversified nature.

ASSOCIATION EXHIBITS

A list "Medical Exhibits Available for Loan" was published in *THE JOURNAL* (Sept. 11, 1937, pp. 32B-36B) which increased markedly the number of requests for exhibits from numerous sources. There are forty exhibits on the list pertaining to the work of the various departments of the American Medical Association or to subjects in which those departments are interested. The material falls into two groups:

exhibits for medical societies and other scientific organizations and exhibits for the public for use at fairs and expositions. Requests from groups other than medical societies are required to come through the secretaries of the county societies or state associations or to receive the approval of such societies. Responsibility for installation and demonstration of the Association exhibits ordinarily is borne by the organization to which the material is lent. The American Medical Association does not have sufficient personnel to accompany all exhibits.

During the year 1937, exhibit material was sent out on 115 occasions to thirty-three states. Often two or more exhibits went to one place, resulting in 250 units distributed during the year. Of the 115 exhibits sent out, forty were medical and scientific in nature and seventy-five were for lay groups.

Attendance at Exhibits—The attendance at fifty-four public meetings was 828,450. The attendance for all groups, including the Great Lakes Exposition and the Texas Pan American Exposition, is estimated as about 3,500,000 persons who actually viewed the exhibits of the American Medical Association during the year.

Exhibit on Syphilis—The Board of Trustees authorized the preparation of an exhibit on "The Treatment of Early Syphilis" in collaboration with the United States Public Health Service. The exhibit was intended primarily for medical societies. It was made in duplicate, one set being sent to Washington for distribution to medical societies in the eastern part of the country and the other set being retained in Chicago to fill requests from the Central West and West. The material has been well received by medical groups and arrangements are in progress whereby exhibits on prenatal syphilis and on late and latent syphilis will be prepared, under the auspices of the United States Public Health Service, for loan purposes under a similar arrangement.

EXPOSITION EXHIBITS

Association exhibits were shown at two expositions during the year 1937, at Dallas and at Cleveland. At Dallas the exhibit was in charge of United States Public Health Service personnel. The attendance was reported to be approximately 1,500,000. The exhibit at the Great Lakes Exposition at Cleveland consisted of eight units. Demonstrations were in charge of personnel furnished by the Cleveland Academy of Medicine. The attendance was reported to be approximately 1,000,000 persons.

MOTION PICTURES

A feature of the motion picture program during the past year was the preparation of the film "The Diagnosis and Treatment of Syphilis—A Motion Picture Clinic." This film was prepared in cooperation with the United States Public Health Service and has been in constant demand. During the last six months of the year when it was available, it was sent out from Chicago on thirty-six occasions. Requests were referred also to the United States Public Health Service at Washington, where there are several copies of the film. Several of the state health departments purchased the film for distribution in their respective states.

Other motion pictures were sent out from time to time. An appropriation has been made for the Council on Physical Therapy to make new films to replace some of those now on hand.

Summary

The Scientific Exhibit at the Atlantic City session was the largest that has been shown, with 254 exhibits. The ratio between the number of exhibits and attendance was the same as for the last several years, approximately one exhibit for each thirty-eight Fellows registered. The Council on Scientific Assembly, the secretaries of the various sections and the section representatives to the Scientific Exhibit all gave close cooperation, while the special exhibits on fractures and anesthesia were outstanding successes.

Association exhibits, dealing with the activities of the Association, were sent out on 115 occasions to thirty-three states. There were forty medical and scientific meetings and seventy-five expositions and fairs for the

public Approximately 3,500,000 persons were reached by such means, including the Cleveland and Dallas expositions

The demand for motion pictures has been constant The new film on syphilis has been received with much favor

Report of Committee to Study Contraceptive Practices and Related Problems

The following report of the Committee to Study Contraceptive Practices and Related Problems has been transmitted, through its Chairman, Dr Carl Henry Davis to the Board of Trustees for submission to the House of Delegates

To the House of Delegates of the American Medical Association

As a supplement to the reports made to you in 1936 and 1937, your committee on contraceptive practices asks your acceptance of the following statement

It is not the function of the American Medical Association to tell physicians what therapeutic advice they shall offer patients However, it has been its policy to investigate various procedures, devices and drugs, and to publish the results of such studies in its official publications for the information of the profession

The instructions to the Council on Pharmacy and Chemistry and the Council on Physical Therapy to investigate further the materials, devices and procedures used for the purpose of contraception do not indicate any change in the usual policy of the Association, nor do they constitute an endorsement by the Association of contraceptive practices

ADDENDA TO REPORT OF BOARD OF TRUSTEES

Report of Committee to Study Air Conditioning

At the time of the San Francisco session of the American Medical Association, the Committee to Study Air Conditioning will have functioned approximately eighteen months From the time of its organization this committee has conceived, as its initial and chief obligation to the Association to the medical profession and to the public, the preparation and publication of basic materials dealing with air conditioning, but foremost with respect to health and comfort By the time of the San Francisco session this committee will have prepared and published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION or will have ready for such publication the following studies Physical and Physiologic Principles of Air Conditioning Part I Physical and Physiologic Principles of Air Conditioning Part II, Equipment for Air Conditioning, Noise and Its Effect on Human Beings Noise Control as a By-Product of Air Conditioning, Hospital Air Conditioning, Instruments Used in the Measurement of Air Conditions In addition, this committee has engaged in the exhaustive compilation of all pertinent publications, both historical and modern, dealing with divers aspects of air conditioning This compilation with its abstracts, representing several thousand titles, is possibly too voluminous for ready publication but is available for scientific purposes and additional research subject to the limitations imposed by possible non-publication

The appraisal of this committee of commercial installations of air conditioning is that, in many instances opportunities for injury to persons subjected to artificial climates exist Fundamentally, these objectionable features are due to faulty concepts of commercial agencies regarding the optimal conditions as to

the atmosphere in which persons may be situated The chief deviations from commendable practices are found in excessive differentials in temperature between outside air and the artificial climate produced by air conditioning, and excesses in air motion This committee, in recognizing that the health of the public may be poorly served by the air conditions provided in many installations, also recognizes that commercial trends are toward greater consideration for the health requirements of persons influenced by artificial climates It is expectable that from the air conditioning manufacturing industry itself will come changes in types of installations to the end that causes of the unfavorable criticism made by this committee relative to many present conditions will be eliminated

On the completion of the publications mentioned, together with the final organization of bibliographic materials, this committee will have completed the program of work undertaken at the time of its creation If these activities fulfil the mission intended for this committee, its discharge is requested Otherwise it will be guided by additional instruction from the House of Delegates or other authoritative body

Report of Committee to Determine the Value of X-Ray Film with Paper Base as a Substitute for Film with Gelatin Base

At a regular meeting of the Board of Trustees held in November 1936 a Committee to Determine the Value of X-Ray Film with Paper Base as a Substitute for Film with Gelatin Base was appointed as follows Dr Hollis E Potter, Chairman, Chicago, Dr Edward H Skinner, Kansas City, Mo, Dr H Kennon Dunham, Cincinnati, Dr J A Myers, Minneapolis, Dr Homer L Sampson, Trudeau, N Y

The Chairman has submitted the following as the report of the Committee

MAJORITY REPORT

Pursuant to your request of Nov 30, 1936, that a stipulated committee study and report on the value of paper base film as a substitute for cellulose or clear base film in x-ray studies of the chest, the undersigned beg to submit the following report The bill for expense is small, largely through the courteous cooperation of the Powers X-ray Products Company, which furnished generous quantities of paper film and developer to each man on the committee, and the Eastman Kodak Company, which furnished the requested number of clear base films, a laboratory assay of the scale of densities in penetrometric units recorded by both types of film, and their series of opaque and clear base films made from the same chests

THE BASIC DIFFERENCES

The essential difference between opaque base film and transparent base film lies not in the character of the emulsion and not in the quality of materials used but in the fundamental fact that the opaque base roentgenogram must be viewed by reflected light, whereas the transparent base film is viewed by transmitted light A secondary difference is that in duplicated clear base film two intensifying screens can be used to advantage, which is not true of the single coated paper film

By increasing the intensity of the transmitted light in viewing translucent base film many details in the areas of deepest blackening are brought to view, whereas in the opaque base film greater light intensity on a blackened area brings forth no new details to the eye

Technically this limitation in paper base film is expressed as a limited scale of density record Under ordinary illumination Wilkey has found that the scale of paper is from 10 to 17 and with translucent film from 10 to 24 With translucent base film the scale is additionally increased by increasing the intensity of the transmitted light when viewing

The practical result of this limited density scale on the part of paper base film is that it has less latitude of exposure, it stands overexposure very poorly, and it fails to give the full scale of density contrast in the heavy individual

CLAIMS

However, the manufacturers of paper base film do not claim its all around equality to transparent base film. They do not "push" it as a substitute for regular film, in which at least a stereo pair is considered a minimum basis for definitive study. They recommend it as a cheaper, efficient medium for use in group chest studies. They consider it quite adequate in the "sifting process" now in vogue in large groups of school children, industrial workers, college students and other social groups. They would consider it a reliable medium to spot out the infected cases, which can then be further studied by x-rays in such more exhaustive manner as desired.

Manufacturers of transparent base film point out the limited density scale of paper base film and emphasize their efforts to increase the scale of their own product to give the inexperienced technician greater latitude for exposure. They mention group surveys in which a high percentage of both opaque and clear base films have to be thrown out because of poor technical handling. They, however, would be pleased to manufacture the paper base product if it should meet with a general demand.

FINDINGS

Your Committee desires to approve of paper base film for all such chest studies as lie well within its scope of reliability and usefulness, with the following reservations:

1 We believe it is possible to miss a small percentage of minimal tuberculous lesions in the use of clear base film and that a somewhat larger percentage of minimal lesions are bound to be missed in the use of paper base film. These minimal lesions are fortunately not a high percentage of those found in any chest survey.

2 Understanding the aforementioned limitations in paper base film, we would believe its greatest field of usefulness to lie in the "group sifting" process as carried on among children in public and private schools, up to a body weight of about 150 pounds. For this purpose we believe the paper film to be infinitely better than no film at all. We cannot but be influenced by the scores of testimonial letters stating the results of group chest surveys by paper film in many cities and states. Some of these have been checked and verified by clear base film.

3 We believe that the narrower density scale of paper base film is not such as to prevent one with a good technic from doing a useful and reliable survey of the chests of thin and medium weight adults. In institutions it has been found valuable in following up known lesions. Where "extent of involvement" is the only problem, paper film may answer very well. To depict the "character of a lesion" and to gain information which will most valuably aid in determining the "type of a lesion," its "prognosis," "arrest," "tendency toward healing," and so on, no x-ray method has been devised that will approach a periodic check with stereo films of the clear base type.

We further believe that when the presence of a lesion has been demonstrated by paper film a more exhaustive study should be made on clear base film.

4 For individual or group chest study of individuals of portly character or body weight beyond 150 pounds the narrow scale of density record in opaque base film presents difficulties which increase in rapid measure as body weight and chest wall increases. The higher voltage required means lack of contrast, and scattered rays have an important role. Results are obtained which cannot be reliably depended on when speaking of the minor grades of tuberculosis or occupational disease. Not only the character but even the presence of a lesion may be indeterminate. Your Committee realizes the limited usefulness of paper film in heavy individuals and discourages its use.

5 The matter of cost. Paper is definitely cheaper. Any discussion of total costs in group surveys must include cost of exposing and processing. Costs with either opaque or clear base film can be greatly reduced by clever devices especially adapted to the problem. We find that for handling paper film

more ingenious devices have been developed for group work than are ordinarily used in connection with clear base film. These devices however are not suitable for the study of individual cases or small groups.

Your Committee regrets that no simpler answer can be agreed on in this rather technical and complex problem.

Respectfully submitted

HOLLIS E. POTTER, Chairman.

H. L. SAMPSON

MINORITY REPORT

OF DR. KENNON DUNHAM

Dr. Dunham approves the report in general but wishes the paragraph numbered 1 under "Findings" to contain his impressions as to the percentage importance of missing early lesions by paper film.

He writes as follows: "If possible, I would like to have you embody one thought of which I have previously written you. I recommend that we emphasize the fact that the few lesions overlooked by a paper survey are quite large in proportion."

"Let us assume that six pulmonary lesions have been found in one thousand examinations, and that paper only overlooked two. That is not two to a thousand, but two out of eight, or a fourth of the lesions. I am certain that this is not an exaggeration, because taking early known lesions as shown by films, and retaking them by paper and single films we completely overlooked two out of ten and threw out two cases because I thought that the paper technic might be not good enough. I am sure that the two thrown out showed much better than would generally be used."

"To repeat: Four lesions were overlooked in twelve exposures on paper, which were easily shown on films. When two of the twelve were eliminated, we had two overlooked out of ten. That is not two out of a thousand but two out of ten, or one fifth, or 20 per cent, were completely overlooked—one fifth or one fourth, not 0.002 per cent."

"Such facts should be clearly stated, otherwise advertisements of the value of paper films will be very misleading."

MINORITY REPORT

OF DR. J. A. MYERS

Dr. Myers says: "With few exceptions I feel this report is satisfactory. The exceptions are as follows:

1 In the next to the last paragraph of the section entitled 'The Basic Difference,' discussing 'limited scale of density record,' I fully appreciate the point you have made. However, in actual practice with reference to the detection of tuberculous lesions of significance, I have not found it of any importance. Therefore, I believe that part of the scale of density beyond 17 carries us into a field that is not significant from the standpoint of finding tuberculous lesions, such as the chest specialists are interested in finding. Anything that is detected beyond the scale of density of the paper film is too indefinite to do anything more than arouse suspicion. In other words I do not feel this is a practical point, therefore in the final paragraph under 'The Basic Difference' were omitted. I would be in full agreement with you."

2 In item 1 under "Findings," attention is called to the fact that we miss a small percentage of minimal lesions on both clear base and paper base film. However, it has been my experience that a somewhat larger percentage of significant minimal lesions are missed with paper base than with clear base film. If this statement concerning the missing of minimal lesions on the paper base film could be omitted I would have no objection to signing the report, as far as this paragraph is concerned.

3 In items 3 and 4, body weight of the individual is considered. I do not see how we could place a limit on body weight. For example, in this section of the country we have a great many tall but well built individuals who weigh more than 150 pounds with whom we have no difficulty in procuring excellent chest films on both paper and clear base. On the other hand, with obese individuals I have seen first class technicians fail to produce satisfactory films of the chest on both paper and clear base films. If you could limit

paragraph to obese persons rather than those of over 150 pounds, and point out that difficulty is encountered with both clear base and paper base films, I would be in favor of the statement"

Report of the Committee on Scientific Research for 1937

During the year, seventy applications received consideration and forty-seven grants were made. As heretofore the new grants support research in various fields of medical interest. Almost without exception, the money has been turned over to the financial officer of the institution in which the grantee works, with the understanding that it would be subject to requisitions by the grantee and that an accurate account of the

expenses would be kept. The final or practically final results of work under forty three grants have been published or are in the course of publication. The results of the work under fifteen grants prior to 1937 are being prepared for publication.

Under thirty-one grants prior to 1937, active work is still in progress, in several cases, reports on results have been published. Refunds amounting to \$311 55 have been made during the year of unexpended balances from grants.

The committee recommends that the same appropriation be made for 1938 as for 1937, namely, \$12,500 for grants in aid of medical research and \$1,200 for committee expenses.

The financial statement for 1937 is presented, also brief accounts of grants pending at the end of 1936 and a list of grants made in 1937.

2 INCOMPLETE

A Work under the grant completed account rendered of expenses but results not published fully

Grant 174 1930 Alfred R Roos College of Medical Evangelists Loma Linda Calif \$1453 hay fever pollens in the Southwest

Grant 286 1933 F H Pike Columbia University \$600 the effects of successive experimental lesions of the nervous system

Grant 308 1933 John L Ulrich Johns Hopkins University \$250 the reflex system in the cat See grant 372 1935

Grant 309 1933 Carroll L Birch University of Illinois School of Medicine \$300 assay of urine for ex hormone of the anterior pituitary

Grant 356 1935 Jay C Davis University of Minnesota \$500 coronary flow and lesions of the aortic valves See grant 463 1937

Grant 365 1935 Ludwig A Fmg Stanford University School of Medicine \$500 effect of castration on malignant tumors

Grant 367 1935 Robert Gault and A C Ivy American Institute for the Deaf Blind Evanston Ill \$600 mechanical stimulation of the vibratile organs See grant 412 1936

Grant 372 1935 John L Ulrich Johns Hopkins University \$450 cerebral functions in the action of antagonistic muscles See grant 308 1935

Grant 378 1935 Wallace M Later Georgetown University Hospital Washington D C histopathologic basis of bundle branch block

Grant 382 1935 L Goodman A J Geiger and L Claiborn Yale University \$250 antianemic principle See grant 340 1934

Grant 412 1936 Robert H Gault and A C Ivy American Institute for the Deaf Blind Evanston Ill \$600 stimulation of vibratile organs by mechanical vibrations See grant 367 1935

Grant 418 1936 Frank W Allen University of California \$200 nucleotide of the red corpuscles See grant 464 1937

Grant 428 1936 D B Pfeiffer K Grimson and H Wilson University of Chicago \$200 effect of sympathectomy on blood pressure in dog See grant 476 1937

Grant 430 1936 S W Ranson Northwestern University Medical School \$315 fever producing agents

Grant 431 1936 Benjamin Harrow College of the City of New York \$200 purification of the hyperglycemic factor in urine

B ACTIVE WORK STILL IN PROGRESS

Grant 24 1922 J Isid Williams Rush Medical College Chicago \$700 decreased dextrose tolerance in acute infectious diseases

Grant 277 1933 Gustav Zechel University of Illinois College of Medicine \$260 study of growing malignant cells by moving photomicrographs Zechel Gustav and Morgenster O A Timing Device for Telling Motion Pictures *Science* 81 23 1935

Grant 310 1934 Jay Martin Johns Hopkins University, \$150, study of gastric juice See grant 462 1937

Grant 324 1934 William deB MacVider, University of North Carolina \$285 study of artificial circulation in the kidney

Grant 337 1934 James L O'Leary Washington University, \$245, Loven reflexes

Grant 343 1934 John Guttman Post Graduate Medical School and Hospital \$400 relation between electrical disturbances in cochlea and the sensation of hearing Guttman John and Barrer S E The Electrical Potentials of the Cochlear and Auditory Nerve in Relation to Hearing *Am J Physiol* 120 666 1937

Grant 344 1934 Paul I Dry and W C Langston University of Arkansas School of Medicine \$300 effect of withdrawal of vitamin G from diet of monkeys

Grant 348 1935 Phillips Thygeson State University of Iowa \$400, trachoma and inclusion virus disease of the genito-urinary tract Thygeson Phillips and Mengert W F The Virus of Inclusion Conjunctivitis *Arch Ophth* 15 377 1936

Grant 350 1935 Frederic A Gibbs Harvard University School of Medicine \$100 fiber system in the cat's brain concerned in convulsions Gibbs Erna Leonhardt and Gibbs Frederic Andrews A Purging Center in the Cat's Brain, *J Comp Neurol* 64 209 1936

Grant 355 1935 Royall M Calder San Antonio Texas \$150 mechanism of pneumococcal inflammation

Grant 370 1935 Richard L Crouch University of Missouri \$500, connections of diencephalon

Grant 379 1935 Victor C Myers (Donald E Bowman) Western Reserve Medical School \$650 chemical test for pregnancy

Grant 380 1935 N W Popoff Highland Hospital Rochester, N Y, \$600 arteriovenous anastomosis

Grant 386 1935 E V McCollum Johns Hopkins University \$150 adaptation of the eyes to subdued light and its relation to vitamin A (refund \$19 65)

Grant 388 1935 Tracy J Putnam Boston City Hospital Boston, \$150 effect of low voltage current on nervous system

Grant 397 1936 R T Hanzel Western Reserve University \$150 source of endogenous uric acid and the effects of methylated xanthines on its secretion

Grant 398 1936 George A Emerson West Virginia University, Morgantown \$175 metabolic products of sympathomimetic amines

Grant 401 1936 W T Dawson University of Texas Galveston \$200, toxicity of cardiac glucosides

Grant 402 1936 C H Thienes and I T Samuels University of Southern California \$500 carbohydrate metabolism as influenced by the hypophysis

Grant 407 1936 Ralph I Dorfman Louisiana State University \$250 estrogenic substance in human urine and other estrogenic compounds

Grant 410 1936 H E Egger University of Nebraska, \$200 effect of tetra methyl ammonium gluconate on human cancer

Grant 413 1936 Philip Levine Newark Beth Israel Hospital Newark, N J \$350 bacteriophage action in the dysentery group Levine Philip and Perlstein David Phage Specific Hereditary Factors in B Dysentriae *Sonne Proc Soc Exper Biol & Med* 36 295 1937

Grant 415, 1936 Gordon H Scott Washington University St Louis \$300 lead and aluminum in cerebrospinal fluid

Grant 416 1936 Jern Broadhurst, Teachers College Columbia University \$200 inclusion bodies in the female genital area

Grant 420 1936 Arthur Knudson Albany Medical College \$400, synthesis of cholesterol in the animal body

Grant 423 1936 Alfred Gilman Yale University \$300 physiology of the antidiuretic hormone of the posterior pituitary Gilman Alfred and Goodman Louis The Secretory Response of the Posterior Pituitary to the Need for Water Conservation *J Physiol* 90 113 1937

Grant 427 1936 Helen S Mitchell Massachusetts State College \$300 nutritional cataract in rats

Grant 433 1936 Frederick Lemere Eastern State Hospital Medical Lake Wash \$500 Berger brain rhythms in psychotic patients

Grant 434 1936 Wilbert H McGaw Western Reserve University \$500 sound conduction in fractured bones

Grant 435 1936 Warren O Nelson Wayne University College of Medicine Detroit \$300 effect of synthetic androgenic substances See grant 481 1937 Nelson Warren O and Merkel Charles C Effects of Androgenic Substances in the Female Rat *Proc Soc Exper Biol & Med* 36 823 1937 Nelson Warren O and Merkel Charles C Maintenance of Spermatogenesis in Testis of the Hypophysectomized Rat with Sterol Derivatives *ibid* p 825 Nelson Warren O and Hickman Jane Effect of Oestrone on Hypophyses and Reproductive Organs of Thyroidectomized Rat *ibid* p 828

Grant 436 1936 Albert P Krueger University of California \$300 nature of bacteriophage Krueger A P and Muddell J H Effect of Phage on Electrometric Potential of Susceptible Cells *Proc Soc Exper Biol & Med* 36 317 1937 Krueger A P The Mechanism of Bacteriophage Production *Science* 86 379 1937 Scribner E J and Krueger A P The Effect of NaCl on the Phage Bacterium Reaction *J Physiol* 21 1 1937 Krueger Albert P and Fong Jacob The Relationship Between Bacterial Growth and Phage Production *ibid* p 137

3 DISCONTINUED (No Results Published)

Grant 361, 1935 P L Heintzinger University of Oregon \$100 School \$100 experimental uterine ovarian implants (refund \$48 75)

Report of Committee on Therapeutic Research

The Committee on Therapeutic Research, a standing committee of the Council on Pharmacy and Chemistry, encourages scientific investigations in the field of therapeutics by providing funds for the prosecution of necessary research

During the year 1937 the Committee issued thirty one grants. A detailed list of these grants, together with a list of publications during 1937, and of unexpired grants made before Jan 1, 1937, will be found in the appendix to this report

The following is a list of the investigations conducted with the assistance of grants made by the Committee on Therapeutic Research, reports of which were published during 1937

1 A Capillary Nonpenetrating Microquinhedron Electrode J A Pierce *J Biol Chem* 117 651 (Feb) 1937

2 Does Digitalis Protect Against Diphtheria Toxin, C W Edwards and R G Smith *J Pharmacol & Exper Therap* 61 37 (Sept) 1937

3 The Effect of Barbitol Derivatives on the Electrocardiogram, Robert Hafke and Winona MacCalmont *Am J Physiol* 119 327 (June) 1937

4 The Effect of Ephedrine on Absorption from the Small Intestine Edward J Van Liere David Northrup and Clark K Sleeth *J Pharmacol & Exper Therap* 60 434 (Aug) 1937

5 Determination of Iodine in Ten Cc of Blood by Burnin, in Platinum Combustion Tube with Screw Feed and Distillation J F McClendon A C Bratton and R V White *Proc Soc Biol Chem J Biol Chem* 119 1496 (June) 1937

6 Excitant Action of Morphine on the Long Surviving Decorticated Cat W E Hamburger *Proc Soc Exper Biol & Med* 36 36 (Feb) 1937

7 Clinical Excretion of Bismuth II The Urinary Excretion of Bismuth After Clinical Intramuscular Injections of Sodium Iodobismuthate (Sodium Bismuth Iodide Iodobismutol) and Sodium Bismuth Thiohyalate (Thioisomol) Torald Sollmann H N Cole and Katharine Henderson *Am J Syph Gonorr & Ven Dis* 21 480 (Sept) 1937

8 Clinical Excretion of Bismuth III Fecal and Total Excretion Torald Sollmann H N Cole and Katharine Henderson *Am J Syph Gonorr & Ven Dis* 21 492 (Sept) 1937

9 Clinical Excretion of Bismuth IV The Late Excretion of Bismuth After Cessation of Treatment Torald Sollmann, H N Cole and Katharine Henderson *Am J Syph Gonorr & Ven Dis* 21 506 (Sept) 1937

10 Tolerance Tests with Ferric Chloride on Advanced Tuberculous Patients Vally Menkin *Am Rev Tuberc* 35 134 (Jan) 1937

11 Studies on Inflammation XIII Carbohydrate Metabolism Leuc Acidosis, and the Cytological Picture in Inflammation Vally Menkin and Charlotte R Warner *Am J Path* 12 25 (Jan) 1937

12 Mechanism of Inflammation, Vally Menkin *Arch Path* 21 65 (July) 1937

13 Isolation and Properties of the Factor Responsible for Increased Capillary Permeability in Inflammation Vally Menkin *Proc Soc Exper Biol & Med* 36 164 (March) 1937

14 Studies of Blood Formation in the Fetus and New Born IV M M Wintrobe and (by invitation) Dean A Clarke William Trager and Louis Danziger *J Clin Investigation* 16 667 (July) 1937

15 The Effect of Immune Blood on the Opsonocidal Power of the Blood in Pertussis William I Bradford Robert Mikell and Betty Slavin *J Clin Investigation* 16 829 (Sept) 1937

16 Absorption of Insulin from Thirty Vella Loops of the Intestine in Normal and Dephosphorylated Dogs John R Murlin Ruth Latta Tembouman and H B Pierce *Am J Physiol* 120 733 (Dec) 1937

17 The Effect of Hexylresorcinol on the Absorption of Insulin from the Gastro-Intestinal Tract of Dogs R G Danks W R Murlin and J R Murlin *Am J Physiol* 120 744 (Dec) 1937

18 The Effect of Estrin on the Basal Metabolism Rate and the Nervous Symptoms of Ovariectomized Women, Mary E Collett Joseph T Smith and Grace E Wertenberger *Am J Obst & Gynec* 31 639 (Oct) 1937

19 Studies in the Metabolism of Alkalinized Dextrose John C Jr Ruth Wuser C Jelleff Carr Frances Beck and T Nelson Carey *Arch internat de pharmacodyn et de therap* 55 9 (Jan 31) 1937

20 The Effect of Decolin Sodium on the Intact Intestine of the Anesthetized Dog Charles M Gruber *J Pharmacol & Exper Ther* 50 301 (March) 1937

21 The Effect of Histamine on Salivary Secretion O S Collins and H H McClanahan *J Pharmacol & Exper Therap* 61 218 (Oct) 1937

22 Studies of the Principle of Liver Effective in Pertussis and Acute IV The Therapeutic Principle of Its Multiple Factors Edward J Merson and Y Subbarow *J Clin Investigation* 16 573 (July) 1937

- 23 Blood Substitutes William A Amberson *Biol Rev* 12 48 1937
- 24 Further Studies on Intoxication with Vitamin D I E Steck H Deutch C I Reed and H C Struck *Ann Int Med* 10 951 (Jan) 1937
- 25 Grenz Rays in Dermatology Cleveland White *Arch Phys Therapy* 18 139 (March) 1937
- 26 The Influence of Cold on the Calorigenic Action of Dimetrophenol V E Hall J M Crismon and P E Chamberlin *J Pharmacol & Exper Therap* 59 195 (Feb) 1937
- 27 Studies on the Sex Difference in Rats in Tolerance to Certain Barbiturates and to Nicotine Harald G O Holck Munir A Kanan Lucille M Mills and Edwin L Smith *J Pharmacol & Exper Therap* 60 323 (July) 1937
- 28 Studies on the Sex Difference in Rats in Tolerance to Certain Barbiturates and to Nicotine Harald G O Holck Munir A Kanan Lucille M Mills and Edwin L Smith *Skandina Arch f Physiol* 77 197
- 29 Chronic Acetanilid Poisoning in the Albino Rat An Experimental Study of Addiction and Tolerance E J Stanton and W R Agricola *J Pharmacol & Exper Therap* 59 437 (April) 1937
- 30 Insulin Treatment of Morphine Abstinence Symptoms An Experimental Evaluation E J Stanton *J Pharmacol & Exper Therap* 60 387 (Aug) 1937
- 31 The Chemotropic Attraction of Leukocytes by Tractions of Streptococcus Haemolyticus H M Dixon M McCutcheon and E J Czarnetzky *Ann J Pathol* 13 645 (July) 1937
- 32 Chemotropism in Leukocytes The Source of the Attractive Substance M McCutcheon and H M Dixon *Arch Path* 23 743 (May) 1937
- 33 The Serum Carotene in Diabetic Patients George H Stueck Gerald Flaum and Elaine P Ralli *J A M A* 109 343 (July 31) 1937
- 34 Experimental Radium Poisoning II Changes in the Teeth of Rabbits Produced by Oral Administration of Radium Sulfate Maurice Rosenthal *Am J M Sc* 193 495 (April) 1937
- 35 A Cinematic Study of Bronchiolar Reactions Torald Sollmann and A J Gilbert *Proc Soc Exper Biol & Med* 36 16 (Feb) 1937
- 36 Microscopic Observations of Bronchiolar Reactions Torald Sollmann and A J Gilbert *J Pharmacol & Exper Therap* 61 272 (Nov) 1937

During 1937 the following grants were made

- Grant 306 Edwards A Park professor of pediatrics Johns Hopkins University School of Medicine \$75 to investigate rickets in the rat and the effect of parathyroid extract on the circulation of the bone
- Grant 307 Ephraim Shorr assistant professor of Medicine Cornell University Medical College \$200 to investigate methods of determining adequate dosage of corpus luteum hormone for the human being
- Grant 308 Claus W Jungeblut professor of bacteriology Columbia University College of Physicians and Surgeons \$250 to investigate the relation of vitamin C to diphtheria
- Grant 309 Katharine Henderson Department of Pharmacology Western Reserve University School of Medicine \$250 to investigate bismuth absorption on oral administration
- Grant 310 Vali Menkin Department of Pathology Harvard Medical School \$150 to investigate the relation of iron salts in the treatment of tuberculosis
- Grant 311 Clarence P Berg assistant professor of biochemistry State University of Iowa \$250 to investigate amino acids
- Grant 312 W F Hamilton professor of physiology and pharmacology University of Georgia School of Medicine \$125 to investigate the effect of anesthesia on vasomotor responses
- Grant 313 Treat B Johnson Sterling professor of chemistry Yale University \$250 to investigate pyrimidines
- Grant 314 F C Koch chairman Department of Physiological Chemistry and Pharmacology University of Chicago \$250 to investigate provitamin D
- Grant 315 Erwin E Nelson professor of pharmacology Tulane University School of Medicine \$125 to investigate some actions of the pituitary
- Grant 316 Edward Van Liere professor of physiology West Virginia University School of Medicine \$100 to investigate the action of various drugs on gastric motility
- Grant 317 Arnold De M Welch Department of Pharmacology Washington University School of Medicine \$250 to investigate the action of choline etc on the metabolism of fat
- Grant 318 Abraham White Department of Physiological Chemistry Yale University School of Medicine \$200 to investigate the lactogenic substance isolated in the pituitary
- Grant 319 J P Quigley Department of Physiology Western Reserve University School of Medicine \$250 to investigate gastrointestinal motility
- Grant 320 M L Tainter professor of pharmacology Stanford University School of Medicine \$250 to investigate sympathomimetic amines
- Grant 321 Helen Tuker Department of Chemistry Skidmore College \$150 to investigate the experimental production of fatty livers by dietary means

Grant 322 George H Paff Department of Anatomy Long Island College of Medicine \$70 to investigate an assay method for digitalis

Grant 323 Torald Sollmann dean and professor of pharmacology and materia medica Western Reserve University School of Medicine and Joseph Seifter Western Reserve University School of Medicine \$250 to investigate bismuth compounds

Grant 324 Howard B Lewis professor of biological chemistry University of Michigan Medical School \$200 to investigate selenium salts

Grant 325 Walter E Hambourger assistant professor of pharmacology Western Reserve University School of Medicine \$150 to investigate the mechanism of morphine action with special reference to the excitement in cats

Grant 326 R Beutner professor of pharmacology Hahnemann Medical College \$80 to investigate the toxicity of procaine

Grant 327 Eben J Carey dean and professor of anatomy Marquette University School of Medicine \$250 to investigate the pharmacologic agents that influence the histologic signs of nervous action

Grant 328 Donald E Gregg assistant professor of physiology Western Reserve University School of Medicine \$250 to investigate the cardiac blood supply in dogs

Grant 329 Roberta Hafkesbring associate professor of physiology Woman's Medical College of Pennsylvania \$250 to investigate the effects of sodium barbital sodium amylal and pentobarbital sodium on blood pressure respiration and kidney function

Grant 330 John B Lagen research associate in medicine University of California Medical School \$150 to investigate the potassium and sodium ions in the blood of patients suffering from asthma and other allergic conditions and changes following treatment

Grant 331 John B Lagen research associate in medicine University of California Medical School \$100 to investigate the total base content of the blood in the anxiety states

Grant 332 J P Simonds Department of Pathology Northwestern University Medical School \$200 to investigate the selective activity of toxic substances on the kidneys

Grant 333 Owen S Gibbs chief of Pharmacological Division University of Tennessee College of Medicine \$180 to investigate the toxicity of morphine and scopolamine on rats

Grant 334 J F McCleendon professor of physiologic chemistry University of Minnesota Medical School \$200 to investigate iodine determination in blood

Grant 335 E M K Geiling professor of pharmacology University of Chicago Paul R Cannon professor of pathology University of Chicago and C M Marberg Department of Pathology University of Chicago \$250 to investigate the fate and mechanism of action of diethylene glycol

Grant 336 E M K Geiling professor of pharmacology University of Chicago Paul R Cannon professor of pathology University of Chicago J M Coon and A Rodaniche Department of Pharmacology University of Chicago \$250 to investigate the fate of sulfanilamide after (1) injury to the liver and kidneys by diethylene glycol (2) the injection of the elixir of sulfanilamide (Massengill)

The following grants were issued before Jan 1, 1937 In some cases the grant has expired and an unexpended balance remains or the work is not yet completed or not yet published

Grant 102 C W Greene professor of physiology and pharmacology University of Missouri \$250 to investigate the distribution of nitrous oxide and oxygen in the blood during anesthesia

Grant 119 Nicholas Kopeloff research associate in bacteriology New York State Psychiatric Institute and Hospital \$100 to investigate bacillus acidophilus milk for the prevention and treatment of summer diarrhea in babies

Grant 152 C W Greene professor of physiology and pharmacology University of Missouri \$300 to investigate the reaction of the coronary system to drugs

Grant 164 E L Jackson associate professor of pharmacology Emory University School of Medicine \$200 to investigate the antagonism between soluble barbital and insulin

Grant 200 Walter Bauer Massachusetts General Hospital Robert W Lovett Memorial Foundation of the Harvard Medical School \$250 to investigate the anatomy and physiology of normal joints with special reference to rheumatoid arthritis

Grant 201 George R Cowgill associate professor of physiologic chemistry Sterling Hall of Medicine Yale University \$250 to investigate vitamin B in relation to morphine addiction

Grant 214 E A Park professor of pediatric and J A Pierce Johns Hopkins University School of Medicine \$200 to investigate the reaction of cartilage

Grant 221 John G Reinhold Department of Public Health Philadelphia General Hospital \$200 to investigate the action of aminoacetic acid (glycine) in proper muscular dystrophy

Grant 222 Eugene L Stull assistant professor of physiology University of Chicago \$200 to investigate the changes in the metabolism of the pancreas

Grant 22 Clinton H Thorne professor of pharmacology and Lawrence E Detrick Department of Pharmacology University of Southern California School of Medicine \$200 to investigate withdrawal phenomena in morphine addicted animals

Grant 228 Henry G Barbour associate professor of pharmacology and Toxicology Yale University School of Medicine \$250 to investigate metabolism and water exchange in morphine habituation

Grant 232 George R Cowgill associate professor of physiologic chemistry Yale University School of Medicine, \$250 to investigate the heart in vitamin B deficiency

Grant 236 C W Greene professor of physiology and pharmacology University of Missouri School of Medicine \$100 to investigate the pharmacology of the so called specific coronary dilator drugs

Grant 238 Roy R Kracke professor of pathology Emory University School of Medicine \$250 to investigate the effect of the oxidation products of aminopyrine and related drugs on the leukocyte counts of rabbits

Grant 248 Fred C Koch chairman of the Department of Physiological Chemistry and Pharmacology University of Chicago \$250 to investigate the testis hormone

Grant 249 J Percy Baumberger associate professor of physiology, Department of Physiology Stanford University \$200 to investigate the occurrence and oxidation reduction potential of pigments in tumor cells

Grant 251 Bernard Fantus professor of therapeutics University of Illinois College of Medicine \$100 to investigate the titration of the anti toxic value of serum of patients who have received tetanus antitoxin

Grant 257 O W Barlow formerly assistant professor of pharmacology Western Reserve University School of Medicine \$150 to investigate epileptics vs barbiturates

Grant 259 O W Barlow formerly assistant professor of pharmacology Western Reserve University School of Medicine \$100 to investigate the effects of parasympathetic drugs on intestine

Grant 261 Robert P Walton professor of pharmacology University of Mississippi School of Medicine \$100 to investigate the absorption of drugs through oral mucosa

Grant 263 H A Shoemaker associate professor of biochemistry and pharmacology C E Clymer professor of clinical surgery and Henry H Turner University of Oklahoma School of Medicine \$150 to investigate the blood cholesterol and iodine values in thyroid disease and their alteration by treatment

Grant 264 Detlev W Bronk Johnson professor of biophysics University of Pennsylvania School of Medicine \$200 to investigate the action of various drugs on the autonomic centers

Grant 268 Walter E Hambourger assistant professor of pharmacology Western Reserve University School of Medicine \$250 to investigate the mechanism of morphine action with special reference to the excitement in cats

Grant 269 Francis G Blake Sterling professor of medicine and Marion E Howard Sterling Professor of medicine Yale University School of Medicine \$50 to investigate the use of artificial pneumothorax in the treatment of lobar pneumonia

Grant 270 Elaine P Ralli assistant professor of medicine New York University College of Medicine \$250 to investigate the effect of carotene on the blood vitamin A

Grant 273 Marston T Bogert professor of chemistry Columbia University \$100 to investigate the chemistry and pharmacology of the quinazoline group

Grant 276 Eugene Stanton Department of Pharmacology Western Reserve University School of Medicine \$150 to investigate the addiction tolerance and abstinence to various narcotics in animals especially rats

Grant 278 William H Lewis Jr assistant clinical professor of medicine, and Arthur C DeGraff professor of therapeutics New York University College of Medicine \$150, to investigate the function of the heart in relation to age

Grant 279 Norman A David assistant professor of pharmacology University of Cincinnati College of Medicine \$65 to investigate the effects of carbarsone and other pentavalent arsenicals on the optic nerve

Grant 280 John P Peters professor of medicine Yale University School of Medicine \$200 to investigate by means of intravenous pyelography the state of ureters and kidneys in a large series of patients after delivery and subsidence of acute signs of toxemia

Grant 281 O W Barlow formerly assistant professor of pharmacology Western Reserve University School of Medicine \$125 to investigate circulatory effects of metrazol under conditions of anesthesia with ether as well as under the influence of hypnotics

Grant 282 Arthur W Grace Department of Medicine Cornell University Medical College \$250 to investigate the effect of x ray and Frei vaccine therapy in artificially inoculated venereal lymphogranuloma in guinea pigs

Grant 283 Louis N Katz director of cardiovascular research Nelson Morris Memorial Institute for Medical Research Michael Reese Hospital Chicago \$200 to investigate the action of drugs on coronary circulation

Grant 285 Morton McCutcheon associate professor of pathology University of Pennsylvania School of Medicine \$150 to investigate the chemotropism of leukocytes

Grant 287 M L Tainter professor of pharmacology Stanford University School of Medicine \$250 to investigate sympathomimetic amines

Grant 288 Louis Goodman Department of Pharmacology and Toxicology Yale University School of Medicine \$150 to investigate the effects of histidine injections on gastric physiology

Grant 289 Carl C Pfeiffer Department of Pharmacology University of Chicago \$225 to investigate the possible amino acids present in the Trypanosoma lewisi antibody

Grant 295 Torald Sollmann dean and professor of pharmacology materia medica Western Reserve University School of Medicine \$200 to investigate the microscopic reactions of the bronchioles to drugs and anaphylaxis

Grant 297 Melvin Dresbach Harvard University Medical School \$250 to investigate the emetic effect of some of the digitalis bodies.

Grant 298 Kenneth W Thompson Department of Physiology University School of Medicine \$200 to investigate the effects of thyroid stimulating hormone

Grant 302 Mary E Collett Flora Stone Mather College Western Reserve University \$200, to investigate the effect of the ovarian hormone on the hot flashes and the basal metabolism of ovariectomized women.

Grant 303 Arnold De M Welch Department of Pharmacology Washington University School of Medicine \$200 to investigate the action of choline and betaine in the metabolism of fat

Grant 304 Howard B Lewis professor of biological chemistry University of Michigan Medical School \$175 to investigate selenium salts.

Grant 305 Beverly Douglas assistant dean and associate professor of surgery Vanderbilt University School of Medicine \$250 to investigate the pneumatic (transparent rubber jacket) system of treating extensive wounds

HERMAN L KRETSCHMER, Treasurer

AUDITOR'S REPORT

February 2, 1938.

To the Board of Trustees,

American Medical Association, Chicago, Illinois

Dear Sirs

In accordance with your instructions, we have made an examination of the Balance Sheet of the American Medical Association, Chicago, Illinois, as at December 31, 1937, and of the Income Account for the year 1937. In connection therewith, we examined or tested accounting records of the Association and other supporting evidence, and obtained information and explanations from officers and employees of the Association, we also made a general review of the accounting methods and of the operating and income accounts for the year, but we did not make a detailed audit of the transactions. We now submit our report on the examination, together with related statements as enumerated in the index appended hereto. In our opinion, based on such examination, the accompanying Balance Sheet and related Income Account fairly present the position of the Association as at December 31, 1937, and the results of its operations for the year, subject to the following qualifications and observations:

- (1) The inventories of materials, supplies and work in progress, amounting to \$92,151 50, are stated in accordance with certificates sworn to by responsible officials of the Association and have not been confirmed by us in any way.
- (2) In accordance with the established practice of the Association, the accounts as stated do not include (a) unrecorded assets in respect of accrued interest on bond investments and membership dues unpaid, and (b) provision for accrued payroll, accrued property taxes for the year 1937, and unpaid bills.

(3) Subscriptions paid in advance are stated at an estimated amount which is based on cash received in December 1937 on account of 1938 subscriptions. This procedure conforms to the method used in prior years.

(4) Advance payments on publications include an estimated amount (\$127,118 58) for prepaid subscriptions to Hygeia, and the amount (\$25,580 50) received in advance for January 1938 advertising, postage and directory sales and service.

(5) The buildings of the Association are carried at reproduction values as determined by an appraisal by Holabird and Root as at December 31, 1936, less depreciation accrued to the date of the Balance Sheet. The portion of the depreciation provision for the year applicable to the increase in book value, which was recorded at December 31, 1936, as determined by the appraisal, has been charged against the complementary credit included in the Net Worth of the Association in that connection.

We have received a letter from Messrs Loesch, Scofield, Loesch and Burke, attorneys for the Association stating that there were two lawsuits pending against the Association at December 31, 1937, both alleging libel, one filed by Dr. Jean Paul Fernel for \$1,000,000, and the other filed by Harold F. Wadlow for \$150,000. The attorneys state that in their opinion both suits will be defeated. We have also received a certificate from an official of the Association stating that at December 31, 1937, there were no contingent liabilities except the lawsuits here referred to.

Fidelity insurance is carried against the undermentioned officers and employees of the Association in the amounts stated:

| | |
|---|--------------------|
| Dr. Olin West Secretary and General Manager | \$10 000 00 |
| Dr. Herman L. Kretschmer Treasurer | 10 000 00 |
| E. A. Hoffman Cashier | 10 000 00 |
| J. E. Hartigan Assistant Cashier | 2 000 00 |
| Sundry Employees (eleven \$1 000 00 each) | 11 000 00 |
| Total Fidelity Insurance | <u>\$43 000 00</u> |

We have pleasure in reporting that the books are well maintained and that every facility was afforded us for the proper conduct of the examination.

Yours truly, PEAT, MARWICK, MITCHELL & Co

REPORT OF THE JUDICIAL COUNCIL

To the Members of the House of Delegates of the American Medical Association

During the past year but two disciplinary actions of county societies have been brought before the Judicial Council on appeal. These are fewer cases than have been appealed in former years and seem to indicate that more particular attention to procedure has been paid than previously. Reversal of state society actions was not required in either case. The correspondence has steadily increased in volume and in the number of new situations which apparently are not plainly covered in the Principles of Medical Ethics. More questions are arising involving the relations of doctors with hospitals, hospital service plans, insurance companies and governmental agencies.

DISCIPLINE BY RESOLUTIONS

The attempt is being made in some societies to regulate some undesirable situations by amendment of the by-laws by the adoption of resolutions or by the establishment of rules of conduct directed to the specific undesirable practice existing at the moment. In such instances small regard is paid to the established constitution and by-laws and short cuts to disciplinary action are sought, usually by making loss of membership automatic on violation of the newly adopted by-law, resolution or rule of conduct. In previous reports the Judicial Council has called attention to the undesirability of basing disciplinary action on such specific rules or resolutions and especially when the general broad principles of conduct set out in the Principles of Medical Ethics are adequate to cover the situation.

Because loss of membership in a component county society causes loss of membership in the state society and in the American Medical Association as well it would seem advisable to have the causes of loss of membership uniform and the same in all county societies at least in those of each constituent state association. If there were such uniformity in all probability the justness of loss of membership and Fellowship in the American Medical Association because of loss of membership in a component society never would arise. Such a question never yet has arisen but may arise if disciplinary measures are taken on the basis simply of the violation of a resolution or a rule of conduct. For example it is not too great a stretch of the imagination to suppose that a component society, having internal disturbances might at a highly emotional time adopt a Rule of Conduct declaring that practicing in a certain hospital automatically removes a physician from membership in the society. Such a rule obviously would be adopted for

some definite purpose. The purpose might be to embarrass or punish a certain physician or a group of physicians or to bring pressure on the hospital. The physician or physicians or the hospital might be entirely ethical and might not violate any of the regularly adopted by-laws. A serious objection to disciplining under Rules of Conduct is that these regulations generally are adopted in a much less formal manner than by law. Ordinarily they are adopted on the spur of the moment by a majority of those present and voting being required. While such a hypothetical case as presented has not come before the Judicial Council as yet, the extension of the practice of using these regulatory procedures as a basis for disciplining will almost inevitably at some time in the future require the Judicial Council to decide whether a member of the American Medical Association can be deprived of Fellowship and the privilege of membership for nothing more heinous than a local unfortunate situation.

STUDY OF CONSTITUTIONS AND BY-LAWS

In view of the rapidly changing conditions of medical practice, as shown by many letters of inquiry coming to the Council, a careful study of the constitutions and by-laws of both constituent state medical associations and component county medical societies might be advisable to determine whether these instruments have kept pace with the changes involving medical practice which have occurred already or are in the process of occurring. Strictly speaking, the activities of a society or any organization are defined by and restricted to those purposes and the necessary activities to accomplish the purposes, stated in the constitution or the articles of incorporation establishing the organization. The constitutions of most medical societies name as the purpose of the organization the promotion of the science and art of medicine, the protection of the public health, the education of the profession and the uniting with similar organizations to form the American Medical Association. In no constitution, so far as the Judicial Council is aware, is there provision to enter the field of the practice of medicine as an organization either by the actual furnishing of care by the organization or by the control of the methods or the procedure of its members in furnishing care. The House of Delegates has recommended that experiments be made by component societies in methods of caring for low income groups, and many such experiments have been made and are now in operation but apparently without authority in the constitutions and apparently without control by the respective societies except through the Principles of Medical Ethics which might be applicable in individual cases. Local county societies and state associations should have direction of and control over such activities but such control and direction cannot be maintained against opposition unless such activities are included among the purposes for which the societies are organized and operating. The Judicial Council recommends that all state associations carefully review their present constitutions and by-laws with the object in view of such revision as may be necessary to meet present day needs of medical practice and medical organizations.

An interesting departure from the customary method of providing for the disciplining of members by county societies has recently come to the attention of the Council. A state association in revising its constitution and by-laws laid down the rules of procedure for disciplining members in excellent detail and established these rules as those to be followed by all component societies under its jurisdiction. By so doing the component societies are obligated to act under and to proceed according to the by-laws of the state association and have neither the need nor the authority to adopt provisions of their own. The by-laws of the component society thus require only the statement that procedures for the disciplining of members are as stated in the by-laws of the state association. It would appear that this plan of having identical rules of procedure in all component societies of a state established by the state association would obviate some of the appeals which come before the Judicial Council on appeal alleging procedural error.

RENTAL OF RADIUM

A widespread practice of renting radium for the treatment of patients by physicians not owning or being experienced in the use of radium has caused considerable discussion during the past year. Ordinarily instructions in the technic of the use of the radium are sent by the person furnishing it. Sometimes the radium is furnished by a commercial concern, sometimes by a physician owning it. The advisability of the use of such a powerful agency by those not trained in its use and the ethics involved of prescribing and directing its use by a person who has not examined or seen the person on whom it is to be used has come before the Council. As a result of a rather extensive correspondence both from those favoring its use as described and those opposed, the Judicial Council is of the opinion that the prescribing and directing of its use in the case of a patient whom the prescriber has not examined or seen is an unethical medical procedure. The Council recognizes that advice and help in difficult cases is often furnished by those in a position to be of possible or probable assistance but it believes that the great dangers accompanying the use of radium removes that particular remedy from the field of advice without personal contact with the patient.

PHYSICIANS AND CULTISTS

Many inquiries concerning the relations of the various cults to the regular profession have been received. The inquiries pertain particularly to the osteopath and the optometrist. Some of our members are giving lectures in osteopathic and optometric schools and addresses before their societies. Some members are associated by a common waiting room in offices with them. Some members are by mutual agreement professional associates principally in the field of surgery. There are some instances of partnership in practice. All of these voluntarily associated activities are unethical. Such relations certainly do not "uphold the dignity and honor of (our) vocation" or "exalt its standards." In case of emergency no doctor should refuse a sufferer knowledge or skill which he possesses to the sufferer's harm but this is quite a different matter from that of a consultant or practitioner who by consulting or practicing with him assists a cultist to establish himself as competent and on the same basis of medical knowledge as a doctor of medicine. By the very nature of the education and training of each a consultation with a cultist is a futile gesture if the cultist is assumed to have the same high grade of knowledge, training and experience as is possessed by the doctor of medicine. Such consultation lowers the honor and dignity of the profession in the same degree to which it elevates the honor and dignity of the irregular in training and practice. Practicing as a partner or otherwise has the same effect and objection. Teaching in cultist schools and addressing cultist societies is even more reprehensible for such activities give public approval by the medical profession to a system of healing known to the profession to be substandard, incorrect and harmful to the people because of its deficiencies. There hardly can be a voluntary relationship between a doctor of medicine and a cultist which is ethical in character.

FINALITY OF STATE ACTION

The constitutions and by-laws of some constituent associations provide that the action of the Council or other authoritative body of the state association in matters of discipline over its members is final. The Judicial Council calls attention to the incorrectness of this statement, which might and probably has been prejudicial to the rights of some members under disciplinary action. The only interpretation of the statement that can be made is that the action of the state authority is final so far as the state association is concerned. Notwithstanding this statement in the constitutions and by-laws the accused has the right of appeal to the Judicial Council of the American Medical Association by virtue of chapter IX, section I of the By-Laws of the American Medical Association reading in part as follows:

The Judicial power of the Association shall be vested in the Judicial Council whose decision shall be final. This power shall extend to and include:

In all cases which arise (c) between a member or members and the component society to which said member or members

belong the Judicial Council shall have appellate jurisdiction in questions of law and procedure but not of fact and also The Judicial Council shall have jurisdiction on all questions of ethics and in the interpretation of the laws of the organization.

It is the opinion of the Council that wherever a statement of finality of the action of the state authority is made the wording should be amended by the addition of the words "except as provided in the By-Laws of the American Medical Association," or some similar phrase.

Respectfully submitted

REPORT OF THE COUNCIL ON MEDICAL
EDUCATION AND HOSPITALS

To the Members of the House of Delegates of the American Medical Association

1 Reports from a large number of medical schools indicate that, as a result of the Council's survey, substantial improvements are being made in faculty personnel, student selection, clinical facilities, buildings and equipment. Nineteen schools have reported budget increases which average \$43,300.

2 The Council is now preparing a final report of the survey which will present a fairly comprehensive review of medical education based on the extensive data collected during the past three or four years. Such a commentary will inevitably become an invaluable source of information to all who may be interested in medical teaching and will constitute a permanent record of the Association's unparalleled contributions in the field of professional education.

3 In May 1936 the House of Delegates adopted a report of the Reference Committee on Medical Education as follows:

Your committee commends the plans for the study of graduate training of physicians in the various phases and regards graduate training as one of the most pressing problems facing the medical profession at the present time.

During the past year the Council has commenced a study of graduate medical education, a field which is almost boundless and enormously complex. For convenience it has been subdivided into three major categories: Extension Courses, Apprenticeships, and Opportunities for Graduate Study. In the first category are found the educational programs of county and state societies together with many other similar activities. The second category consists chiefly of internships and residencies, the modern equivalent of the old fashioned apprenticeships. Under the caption "Opportunities for Graduate Study" will be listed those offerings, for the most part under university auspices, which, though not necessarily leading to a degree, conform to the generally accepted standards of graduate work.

4 Since the last meeting of the Association, the Council has begun to inventory the field of extension courses. When the House of Delegates meets, eighteen states will have been visited for the purpose of gathering data. Each state has peculiar problems which must be individually studied and solved. State societies, departments of health, medical schools and foundations may all be more or less concerned in planning and administering such courses. The federal government, through its social security funds, is now actively entering this field. The officers of the respective state societies must be alert and energetic if the medical profession is to retain its control over this most important function.

5 During the Atlantic City session the Advisory Board for Medical Specialties undertook to create a "Commission on Graduate Medical Education." This commission it was stated would not undertake to inspect or appraise institutions engaged in graduate teaching nor would it invade the sphere of action of the Council. Dr. Robert Buerki of Madison, Wis., will be director of the commission's studies.

6 Patients in 1937 entered hospitals at the rate of one every 34 seconds. The rate of growth in hospitals is equivalent to one hospital of seventy-six beds for each day. Sundays and holidays included. New hospitals in addition to the 6,128 already

registered include 100 hospitals opened but whose registration is pending, seventy under construction, and 179 planned and being developed. The rate of occupancy in general hospitals is 70 per cent of capacity. There are 6,128 hospitals, 1,124,548 beds, 55,566 bassinets, 932,912 births, 944,436 average census, and 9,221,517 patients admitted, of which 2,509,925 were in governmental hospitals and 6,711,592 were in nongovernmental hospitals. Thus nearly three fourths of the patients are cared for in private hospitals having only about one fourth of the bed capacity of all hospitals in the country.

7 In accordance with the resolution of the House of Delegates adopted at the 1934 session, the Council is proceeding with its analysis of the attending staffs of approved hospitals. A constantly increasing number of such institutions have made membership in the county society a prerequisite for staff appointments.

8 The Standard Nomenclature of Disease, now published by the Association, is being advocated in all cases in which hospitals are at liberty to consider the adoption of a new terminology. The ultimate advantage of uniformity in this respect needs no special comment.

9 The Mental Hospital Survey Committee has requested and received the effective cooperation of the Council. An officer of the committee has spent considerable time at Association headquarters studying our records, and the secretary of the Council has considered with Dr. Walter L. Treadway, chairman of the committee, means of securing additional data concerning the mental hospitals.

10 In considerable numbers, students unable to secure admission to medical schools in this country or in Canada still migrate to European countries and, after completing a medical course, return to the United States to practice. The problem is aggravated by the large number of foreign born physicians now seeking asylum over here. Some states complacently accept foreign credentials at their face value. Others write to the Council for an evaluation of such documents. Obviously, the American Medical Association has no means of securing official reports from European schools or of making personal inspections, and it is therefore utterly impossible for the Council to underwrite or guarantee the education of a medical student trained abroad. The state of California has passed a law that in order to be eligible for the license examination all candidates presenting foreign credentials must spend at least one year in an approved hospital or medical school in the United States.

11 It is thirty-one years since the publication of the Council's first classification of medical schools. Although all but one of the states have statutory authority to exclude from the licensing examination the graduates of low grade medical schools, in 1937 there were 233 such graduates licensed in thirteen states. It would seem that state medical societies might be more active in demanding that the standards of our profession be upheld and the interests of the public protected by restricting the privilege of licensure to those known to have been trained in first class medical schools.

12 Within the year, two have been added to the Council's staff, Dr. Hamilton H. Anderson and Dr. Stuart P. Cromer. The latter succeeds Dr. Carl M. Peterson, who has become Secretary of the Council on Industrial Health.

13 The Council has prepared exhibits for the conventions of the American College of Surgeons at Chicago, the American Hospital Association at Atlantic City, the Catholic Hospital Association at Chicago, the Tri-State Hospital Association at Chicago, the New England Hospital Association at Boston, a Hospital Bazaar at Cumberland, Md., and at the Capitol Theater, Davenport, Iowa, in addition to the Atlantic City session, and has been officially represented at the inauguration of President Rufus C. Harris of Tulane University and President Oliver C. Carmichael of Vanderbilt University.

14 As usual, the Council has prepared material for special issues of THE JOURNAL—the Educational Number, Aug. 28, 1937, the Hospital Number, March 26, 1938, and the State Board Number, April 23, 1938. It has contributed to the revision of the Interns' Handbook and published the Proceedings of the Annual Congress on Medical Education and Licensure. For the Fifteenth Edition of the American Medical Directory, the Council has revised the data on hospitals and medical schools.

15 During the year ended March 31, 1938, 319 hospitals have been visited, nine medical schools and fourteen schools for training of technicians.

16 The Council has cooperated with the Bureau of Exhibits in preparing material for the 1939 fair at San Francisco at New York.

17 Some changes have been found necessary in the format of an Acceptable School of Occupational Therapy. In revised form they are submitted for ratification.

Respectfully submitted

REPORT OF THE COUNCIL ON SCIENTIFIC ASSEMBLY

To the Members of the House of Delegates of the American Medical Association

The Council on Scientific Assembly has given official attention to matters which properly come before it for consideration.

The annual Conference of Section Secretaries with the Council was held in Chicago on Dec. 17, 1937. At this conference the desirability of effecting some changes in the nature of the programs of the sections of the Scientific Assembly was fully discussed, and it is possible that some such changes will be instituted at the next annual session in an effort to vitalize the section programs and to permit important scientific subjects of mutual interest to be presented and discussed at joint meetings of two or more sections. While it is true that in the past symposia participated in by two sections have been presented, it is possible that the interest in the scientific work of the Association may be greatly increased and the value of section programs enhanced through an arrangement that will permit joint meetings participated in by several sections, such meetings to be held on the last day of the Scientific Assembly at each annual session.

At the annual session in 1937 the program of the General Scientific Meetings on Tuesday morning was divided so that in one section the discussions pertained to subjects in the field of general medical practice while in the other section the program was devoted entirely to surgical subjects. This new arrangement met with such enthusiastic response that it will be continued. At the San Francisco session the entire program for Tuesday will be divided into two sections, one dealing with general medicine and the other devoted entirely to the discussion of surgical subjects. The attendance at the General Scientific Meetings and the interest in the programs presented have constantly increased until these meetings now constitute a distinct feature of each annual session. It is the earnest desire of the Council on Scientific Assembly to make these programs as helpful as possible to the rank and file of the profession.

The official program of the San Francisco session is submitted as a part of the report of the Council on Scientific Assembly. The Council desires to express openly its appreciation of the valuable service rendered by the section officers, who have been responsible for the preparation of the section programs.

At a later time during this session the Council on Scientific Assembly will submit to the House of Delegates nomination for Affiliate Fellowship.

Respectfully submitted

SATURDAY, APRIL 30, 1938

THE BLEEDING PEPTIC ULCER

Considerable differences of opinion are apparent as to the incidence, the mortality rates and the treatment of bleeding peptic ulcer. Hurst¹ found the incidence of hemorrhage in all types of peptic ulcer about 27 per cent and the mortality from the same source about 15 per cent in general practice. Since the incidence is 27 per cent, the mortality from hemorrhage in all cases of ulcer is about 0.4 per cent. The mortality in patients with ulcer admitted to Guy's Hospital because of hemorrhage was 48 per cent. The mortality from hemorrhage in patients with a history of hemorrhage is under 2.5 per cent and the mortality from hemorrhage in all cases of ulcer, including those in which bleeding never occurred, is about 1 per cent. Hurst concludes that since the total mortality as the result of all surgical procedures for gastric and duodenal ulcers is much greater than that from hemorrhage in all cases of ulcer, and as hemorrhage is by no means rare after operations on patients with ulcer who have already bled, surgical treatment cannot be regarded as a means of prophylaxis against fatal hemorrhage.

The conservative treatment of bleeding gastroduodenal ulcer consists of rest in bed, morphine, starvation for the first twenty-four hours, salt solutions with or without dextrose by rectum and later by a graduated diet and alkalis. Blood transfusion both as replacement therapy and for its effect on the coagulability of the blood and on hematopoiesis has been widely adopted in this country as an important adjunct to the general conservative treatment. The advantages of administration of large doses of epinephrine, iron and the various hemostatics are negligible.

An interesting and radical innovation was introduced by Meulengracht² of Copenhagen, who reported a sensationally low mortality of less than 1 per cent among 251 patients admitted to Bispebjerg Hospital because of severe hematemesis or melena. He fed his patients an abundant and varied diet in puree form

from the first day of admission to the hospital. He believed that food and alkalis, by neutralizing the gastric acidity, would prevent further penetration by the ulcer and reduce the gastric motility, while the supply of nourishment and vitamins would favor the healing process. Woldman³ reported a series of twenty-one cases of severe gastroduodenal hemorrhage in which treatment by the continuous administration of colloidal aluminum hydroxide by means of a special drip apparatus was successful.

Finsterer,⁴ who for the past two decades has consistently urged the most radical attitude toward bleeding peptic ulcer, believes the remarkable results obtained by Meulengracht were due to the fact that he dealt with superficial ulcers or cases of ulcerative gastritis. He calls attention to the reports of Bulmer, Aitken, Gordon, Gordon-Taylor, Chiesman, Hinton and others whose mortality statistics are in sharp contrast to those of Babey, Hurst and Conybeare. Bulmer⁵ reported, in an analysis of cases treated at the Birmingham Hospital for a period of thirty years, a mortality of 10.7 per cent, the death rate among men being at least double that among women and occurring at rather a later age. Aitken reported a mortality of 47.2 per cent. According to Gordon-Taylor, the mortality in cases of hematemesis from chronic ulcer of the stomach or duodenum treated medically at the Middlesex Hospital from 1924 to 1933, in which a second large hemorrhage took place, was no less than 78 per cent and with each successive bleeding the death rate became higher. Chiesman⁶ reported a mortality of 25 per cent among 191 patients admitted to St. Thomas's Hospital during the period 1925-1931. This mortality was equivalent to that of perforated ulcers in the same group. Bleeding continued or recurred in forty-eight males and in fourteen females twenty-four hours after they came under treatment. Mortality in this group was 74 per cent. Postmortems on forty-five of these revealed that the common cause of repeated hemorrhage was a partially eroded vessel of considerable size in the floor of an ulcer, the type of the ulcer being callous in thirty cases and acute in seven, multiple ulcers were present in other cases. He concludes that, in the group of cases presenting a mortality of 74 per cent, operative treatment might have improved the recovery rate. From the clinical histories and the postmortem observations in these cases it is evident that there is a special form of bleeding ulcer caused by erosion of a large artery and capable after one or two massive hemorrhages of exsanguinating the patient. Bleeding of this type was considered by von Mikulicz a most urgent emergency. Indeed, one is reminded of the classic

² Meulengracht E. Treatment of Hematemesis and Melena with Food. *The Mortality* *Lancet* 2 1220 (Nov 10) 1913.

description by Moynihan of a callous, deeply penetrating duodenal ulcer with exposed stiff arteries. Such bleeding is not likely to stop of itself and waiting is more dangerous than operation. In such cases Finsterer's dictum of operation within the first twenty-four to forty-eight hours has validity and is supported by Gordon Gordon-Taylor, Trier and Clavel, Allen and others. In a series of thirty-five early partial gastric resections performed by Finsterer for severe hemorrhage there was only one death from pneumonia. In a group in which a late operation was performed his mortality amounted to 30 per cent.

The first and most urgent problem then is to determine whether the bleeding comes from a superficial ulceration or from a deeply penetrating ulcer. A history of a long existing ulcer, of persisting severe pains characteristic of penetration and adhesion to a neighboring viscus, and the roentgenologic niche are all evidences of a penetrating callous ulcer. Means would limit operative procedure to patients bleeding after 50 years of age or those having repeated hemorrhages. The problem of the bleeding peptic ulcer is certainly not a case of surgery versus medicine. On the contrary, the cooperation of the internist and the surgeon is most desirable. Each case must be evaluated in the light of its history, roentgenologic appearances, the age of the patient and the type of bleeding. If surgical operation appears to be indicated, it should not be unduly delayed.

FEDERAL FOOD AND DRUG BILL CONDEMNED

The food and drug bill recently reported to the House of Representatives by the Committee on Interstate and Foreign Commerce¹ has been vigorously condemned in a minority report² signed by six members of the committee and in a letter from the Secretary of Agriculture embodied in that report. This condemnation is based primarily on the proposal in section 701 (f) of the bill to empower the United States district courts throughout the country (1) to review certain orders that may be promulgated by the Secretary of Agriculture under authority of the proposed law, (2) to restrain the secretary from putting such orders into effect, and (3) to direct the secretary to take whatever further action the court may think justice requires. Such reviews may be initiated in any one of eighty-three district courts, on the petition of any importer, producer, manufacturer, distributor or dealer in foods, drugs, diagnostic and therapeutic devices and cosmetics who feels that he is aggrieved by the secretary's order. The idea of investing the district courts of the country with such authority as this bill proposes discloses a novel concept of the relations between the administrative, legislative and judicial functions of our government.

This proposal for the enactment of court review legislation savors strongly of the influences that have heretofore prevented the inclusion of adequate standards in any pending legislation relating to drugs and diagnostic and therapeutic devices and that brought about the attenuation of the restrictions on false and fraudulent advertising proposed in such legislation.

Concerning the section of the bill denounced by him, the Secretary of Agriculture says

I am of the opinion that if section 701 (f) remains in the bill its effect will be to hamstring its administration so as to amount to a practical nullification of the substantial provisions of the bill.

It is the Department's considered judgment that it would be better to continue the old law in effect than to enact Section 701 (f) of this provision.

Of the same section of the bill, the minority report of six of the committee members says

If this bill is enacted into law with section 701 (f), the court review section, in it, as reported by a majority of the committee what started out as an effort on the part of the advocates of a more adequate food and drug law to enlarge the scope of the existing law, to fill in the loopholes in it, and to put more teeth into it, will end with having accomplished the directly opposite result and years of earnest effort will have gone for worse than naught.

Official, disinterested denunciations such as these seem to justify a demand by every consumer of foods and drugs and every user of diagnostic and therapeutic devices and of cosmetics that his representative in Congress use his best efforts to prevent the enactment of the food, drug, device and cosmetic bill, S. 5, in the form proposed by the committee. The defeat of the bill in its entirety might not be altogether disadvantageous for it would provide an opportunity for the introduction into later legislation of proper standards for drugs and devices. The delay would provide time also for search for a more promising method of controlling the introduction of new drugs than that proposed in the pending bill.

THE STUDY OF DISEASE AMONG BRITISH POST OFFICE EMPLOYEES

Observations based on the 260,000 employees of all ages and varied activities of the English post office system enabled Bashford¹ to present convincing evidence of the reciprocal dependence of industry and medicine. The post office is unique in that there is in England no other body of industrial workers of anything approaching its size that has accurate sick records analyzed yearly in terms of occupational groups and geographic distribution. The records date from the middle of the last century and hence lend themselves readily to a certain type of study.

The incidence of pulmonary tuberculosis in this group compares favorably with that in the community at large and during the last twenty years has shown a steady downward trend. In an analysis of 3,755 cases observed

¹ S. 5 H. R. Rep. 2139 Part 1 75th Congress Discontinued editorially in THE JOURNAL April 23 page 1370
² S. 5 H. R. Rep. 2139 Part 2 75th Congress

¹ Bashford H. H. The Contribution of Industry to Medicine. F. Roy Soc. Med. 21 183 (Jan.) 1935

over the last twenty years, it was found consistently that in only 50 per cent of all new cases of pulmonary tuberculosis was it ever possible to return to active duty. There was a further wastage of 48 per cent during the following ten years because of recurrent pulmonary tuberculosis or other forms of ill health. A follow-up study of 430 employees with gastric or duodenal ulcer showed that 31 per cent, no matter how treated, incurred regularly at least a month's sick absence every year for recurrent digestive disorders or other forms of ill health. A further 27 per cent had sick absences of shorter periods. This industrially unsatisfactory record should certainly receive close attention. The post office was one of the first pensionable services to accept persons with adolescent or "orthostatic" albuminuria. Thirty years ago Bashford examined a group of thirty and reexamined them after periods of service varying from seven to fourteen years. Twenty per cent still exhibited the condition but were apparently in good health. Seventeen years later, with the exception of three who had left the service for extraneous causes, two who could not be traced and one who had died from acute nephritis, the whole group again was examined and all found in good health.

Bashford includes a brief report of the three year experiment with vaccine in the attempted prevention of colds. The vaccine used contained *Bacillus influenzae*, *Staphylococcus pyogenes*, *Streptococcus pyogenes*, *Pneumococcus* types I and II, *B. coryzae*, *segmentosus* and *B. friedlander*. The colds in adequate control groups were also recorded. The average sick absence from colds among those receiving the vaccine during the first year of the experiment was less by half of one day than that of the noninoculated group. During the second year the average sick absence for such disorders among the inoculated was one-tenth day higher than that in the noninoculated controls, and during the third year two-tenths day higher than that of the controls. While no claim to finality is made, the results indicated definitely that the routine provision of this vaccine against colds for the staff as a whole was not yet a measure that could be justified by the results experienced.

The experiences with quarantine for infectious disease may have far reaching significance. For some years any contact subsequently acquiring infectious disease had to be reported. Of 17,844 contacts with scarlet fever, only one in 251 subsequently acquired the disease. Of 17,436 contacts with measles, only one in 670 became infected, and out of 7,697 contacts with diphtheria, only one in every 274 became ill with that disease.

About 30 per cent of all sickness is included in the respiratory group of disorders, and this is true both for men and for women. About 10 per cent is included in the digestive group and this is again true of both sexes. Surprisingly, about 10 per cent of male illness

was incurred in the rheumatic group of disorders while it is recorded in only 4 per cent of the women. Nervous disorders accounted for 14 per cent of the women's disability but only 6 per cent of the men's absences. Finally there is that vague class of illness which, while there would seem to be no factor of true malingering, suggests a condition of self pity and making much of little. The examination of forty cases of repeated, relatively trivial accumulating sick absences showed an underlying factor of apparently this type. Over a period of four years, these forty people had among them incurred 736 sick absences, totaling 6,194 days. Kindly advice was given that, if these sick records continued, retirement on grounds of persistent ill health would have to be considered. The following six months showed only fifty-four days' sick absence among the whole forty. In other words, their six monthly average of illness dropped abruptly from nineteen to one and three-tenths days per person.

Current Comment

BILE SALTS AND ARTHRITIS

Observations by several clinicians independently that the development of jaundice in certain arthritic patients produced a definite remission in joint symptoms has stimulated two further studies. Hench¹ has just made available the results of clinical and chemical studies on thirty-one patients whose rheumatic symptoms were partially or completely relieved coincidentally with the onset of spontaneous jaundice. The phenomenon appeared to depend more on the quantity than the quality of jaundice, and the concentration of serum bilirubin served as a general index of the degree of relief. The analgesic effect of jaundice was usually noticed within the first three days after the jaundice became readily visible. Twenty-two of the thirty-one new patients obtained complete relief and the other nine were largely if not entirely relieved. Attempts to reproduce the relief by administration of whole bile and certain of its constituents were made. Transfusions of deeply jaundiced blood were tried and jaundice was produced by the administration of toluylenediamine, by these means and with the rather small doses used, the phenomenon of arthritic relief was not reproduced. Thompson and Watt,² reporting also in a recent issue of the *Archives of Internal Medicine*, first noted the effect of administration of various bile constituents on rabbits. Then they gave a patient with chronic nonspecific atrophic arthritis daily doses of 10 mg. of bilirubin per kilogram intravenously for four days and on the fifth, sixth and seventh days added 40 mg. of sodium dehydrocholate per kilogram. After four injections of

2 Thompson H. E. and Watt J. L. Experimentally Induced Jaundice (Hyperbilirubinemia). Report of Animal Experimentation and of the Physiological Effect of Jaundice in Patient with Atrophic Arthritis. *Arch. Int. Med.* **61**: 451 (March) 1938.

bilirubin, slight icterus developed but was not accompanied by relief of symptoms. Within eight hours after the fifth injection, however, definite relief from pain in all the involved joints occurred. The combination of bilirubin and bile salt was then given to eight patients with chronic atrophic arthritis. The combination of bilirubin and bile salt given by the technic which these investigators finally found satisfactory appeared to be effective in the amelioration of symptoms of atrophic arthritis, although neither of the constituents alone produced this effect. Further study and confirmation are required before these observations can be applied generally in the treatment of atrophic arthritis, but the preliminary observations seem most suggestive of a new avenue of approach to this difficult problem. Moreover the similar amelioration of arthritis in some women during pregnancy as recently noted by Hench³ suggests that the agents responsible for both phenomena are at least closely related but that if a chemical substance it is neither bilirubin nor a strictly female sex hormone.

PROPOSED FEDERAL SANCTION OF OSTEOPATHY

Osteopathy will be sanctioned as a method of treating sick and injured federal employees under the United States Employees' Compensation Act, as amended,¹ if a bill² favorably reported to the House of Representatives by its Committee on the Judiciary is enacted. The bill was introduced by Congressman Drew of Pennsylvania, an osteopath. As introduced, it proposed to place osteopaths on the same plane as qualified doctors of medicine, under the United States Employees' Compensation Act, making no reference to the restrictions placed on them by the laws of many of the states in which they practice. The committee, however, in making its report has recommended that such osteopathic treatment as may be rendered under the act, at the expense of the United States government, be limited to treatment tolerated by the laws of the state in which it is administered. However, not every osteopath will be permitted to treat government employees even to that extent, but only such as are designated by the United States Employees' Compensation Commission. The osteopaths of the country have maintained continued pressure to procure the favorable report that has now been made on this bill. They will doubtless continue that pressure in the hope of procuring its enactment. Whether they do or do not succeed will depend on the physicians of the country. If every physician who believes that osteopathy is not a safe method of diagnosing and treating disease and injury protests to his congressman against the enactment of this bill, its defeat will be assured.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

State Medical Meeting at Pasadena May 9-12—The sixty-seventh annual meeting of the California Medical Association will be held at the Hotel Huntington, Pasadena May 9-12, under the presidency of Dr. Howard Morrow, San Francisco. The Los Angeles County Medical Association and its Pasadena branch will act as hosts, with Dr. George H. Lee of Los Angeles, president of the former, delivering the address of welcome. The out of state speakers will include:

Dr. Udo J. Wile, Ann Arbor, Mich., The Relation of Syphilis to Surgical Problems
Dr. Tinsley R. Harrison, Nashville, Tenn., Cardiac Dyspnea
Dr. Alexis F. Hartmann, St. Louis, Studies on Hypoglycemia in Infants and Children
James B. Hamilton, Ph.D., New Haven, Conn., Experimental Production in Animals of Conditions Similar to Those of the Adrenal Syndrome in Humans
Dr. Thomas D. Moore, Memphis, Tenn., The Cystoscopic Implantation of Radium Element in Tumors of the Bladder

Dr. Harrison, with another guest speaker, Dr. Alfred Blacklock, Nashville, will conduct a clinical pathologic conference Tuesday and a symposium on shock. There will also be symposiums on vitamins and nucleus pulposus rupture and its relation to injury. Entertainment will include a trip to Griffith Park Planetarium, golf and a trip to a motion picture studio. The president's dinner will be held Tuesday night.

CONNECTICUT

Changes in Health Officers—Dr. John E. Stoddard has been appointed health officer of Meriden to succeed Dr. Michael J. Sullivan. Dr. Winfield E. Wight is the new health officer of Thomaston, succeeding Dr. James H. Kane, resigned. Dr. Ernest R. Pendleton has been appointed health officer of the town of Granby.

Society News—The New Haven Committee on Social Hygiene has been reorganized under the auspices of the New Haven Foundation and the New Haven Department of Health. The new name will be New Haven Child Hygiene Association. Miss Mary Harkin has been chosen executive secretary. —Dr. Arvid Lindau, professor of general pathology and bacteriology, University of Lund, Sweden, addressed a special meeting of the Yale Medical Society March 24 on "Benign Lymphogranuloma (Sarcoid of Boeck)."

DISTRICT OF COLUMBIA

Annual Scientific Assembly—The Medical Society of the District of Columbia will hold its annual scientific assembly May 4-5 in the Medical Society Building, 1718 M Street N.W., Washington. The out of town speakers on the program include:

Dr. William P. Healy, New York, Carcinoma of the Corpus Uteri: Treatment and Prognosis
Dr. Perrin H. Long, Baltimore, The Mode of Action and Toxicity of Sulfanilamide
Dr. Ramon Castroviejo, New York, Eye Surgery (motion picture)
Dr. Roy Upham, New York, New Trends in Diseases of the Stomach
Dr. Jacob Sarnoff, Brooklyn, Diseases of the Breast (motion picture)
Dr. Paul Titus, Pittsburgh, Human Sterility

A public meeting Wednesday evening will be addressed by Dr. William R. Houston, Austin, Texas, on "Western Medicine in China." Hon. Hutton W. Summers will address the luncheon Wednesday on "Natural Laws in Government." Clinics will be offered and the annual banquet will be Thursday evening at the Mayflower Hotel.

ILLINOIS

Society News—Dr. Marcus Pinson Neal, Columbia, Mo., addressed the St. Clair County Medical Society in East St. Louis April 7 on "Reactive Blood Cells in Acute Infection." —Dr. Arthur Carlton Ernstene, Cleveland, discussed "Differential Diagnosis of Coronary Artery Disease" before the Sangamon County Medical Society, Springfield April 7.

CHICAGO

University News—The John and Mary Markle Foundation of New York City has made a grant of \$10,000 to support research work on neurophysiology for three years under the supervision of Dr. Ernst Gellhorn, professor of physiology, University of Illinois College of Medicine.

The Luckhardt Lecture—Dr Henry E Sigerist, William H Welch professor of the history of medicine Johns Hopkins University School of Medicine Baltimore delivered the Arno B Luckhardt Lecture at Albert Merritt Billings Hospital April 28, his subject was "Principles of Greek Medicine"

Former Mental Patients Form Society—Sixty-four former patients of the Psychiatric Institute of the Illinois Research and Educational Hospitals, University of Illinois, organized the "Association of Former Patients of the Psychiatric Institute of the University of Illinois" at a meeting April 3. Designed primarily to reestablish its members in society, the new organization aims to help the physicians of the institute to study the subsequent adjustment of the patients, to engage in an educational campaign for the purpose of changing the attitude of the community toward mental disease and to promote the economic interest of former patients. The new association plans to form an employment agency and to issue a monthly bulletin. At the time of this report the association had seventy-five members.

INDIANA

Personal—Dr Harry H Botts, medical officer in charge of the Veterans Administration Facility, Veterans Administration Hospital, near Marion, has been transferred to the facility at Chillicothe, Ohio, succeeding Dr Dennis J Murphy. The latter will take over the Marion post.

Society News—Dr Cyrus W Rutherford Indianapolis has been elected president of the Indiana Academy of Ophthalmology and Otolaryngology, succeeding Dr Emory E Holland, Richmond.—The Northeastern Indiana Academy of Medicine was addressed in Kendallville March 31 by Drs Laurence E Hines and James Roscoe Miller, Chicago on diagnosis and treatment of coronary occlusion.—The Indianapolis Medical Society was addressed April 26 by Drs Charles P Emerson on "The Physical Basis of Emotional Disturbances" and Charles R Bird, "Diagnostic Trends and Psychoneurosis." Dr Fred L Adair, Chicago, discussed "Maternal, Fetal and Neonatal Morbidity" before the society March 29.

State Tuberculosis Meeting—The Indiana Tuberculosis Association and the Indiana Trudeau Society met in joint annual session in Indianapolis April 20-21. The speakers included

Dr Philip H Becker, Crown Point. Pneumoconiosis
Dr Robert A Staff, Richmond. Laboratory Diagnosis of Tuberculosis
Dr Paul D Crumm, Evansville. Treatment of Childhood Tuberculosis
Dr Donald W Brodie, Oaklandon. Extrapulmonary Tuberculosis
Dr Mason B Light, Indianapolis. Specular Examination
Dr Jerome V Pace, Rockville. Malignancy of the Lung
Dr Harvey L Murdoch, Fort Wayne. Silicosis

At a general session the evening of April 20 the speakers included Drs Calvin C Applewhite, U S Public Health Service, on "Place of Tuberculosis Control in a Whole Time Health Program" and Robert G Bloch, Chicago, "The Approach to the Tuberculosis Problem."

KANSAS

State Medical Meeting at Wichita—The seventy-ninth annual session of the Kansas Medical Society will be held in the Wichita Forum, May 9-12, under the presidency of Dr Jacob F Gsell, Wichita. The speakers will include

Dr Harold E Robertson, Rochester, Minn., Diseases of the Gallbladder, Bile Ducts and Liver. Practical Considerations
Dr Horton R Casparis, Nashville, Tenn. The Medical Aspects of Child Behavior
Dr William B Carrell, Dallas, Texas. Fractures of the Hip in the Aged with Indications for Nails and Bone Graft
Dr John H J Upham, Columbus, Ohio. President American Medical Association. Economic Aspects of Medicine
Dr Louis J Karnosh, Cleveland. Mileposts in Modern Psychiatry
Dr Thomas D Allen, Chicago. What Kind of Cooperation Should There Be Between the Ophthalmologist and His Colleagues in Other Specialties?
Dr Aaron Arkin, Chicago. Cardiovascular Syphilis. Diagnosis and Therapy
Dr Alfred I Folsom, Dallas. Some Practical Considerations in the Treatment of Chronic Gonorrhea
Dr Vernon C David, Chicago. Some Etiologic Considerations of Cancer of the Large Bowel
Dr Dean D Lewis, Baltimore. The Differential Diagnosis of Bone Tumors
Dr Harold I Illie, Rochester, Minn. General Considerations of the Physiology of the Nose as Pertains to General Practice
Dr Fred E Angle, Kansas City. Undulant Fever—Its Present Clinical Status
Dr Clifford J Mullen, Kansas City. Analysis of Program for the Blind of the Kansas State Board of Social Welfare
Dr Harold W Peters, Topeka. Hearses
Dr La Verne B Spake, Kansas City. Diagnosis and Classification of Surgical Malocclusion
Dr Nile S Powell, Lawrence. Cycloplegics. Mydriatics and Miotics

There will be luncheons and entertainment will include golf and skeet tournaments, a golf and skeet banquet, the alumni

'round-up' Tuesday evening, and the annual banquet Wednesday evening. Radio talks for the public will be delivered during the week. The Sedgwick County Medical Society will be host to the state meeting and will sponsor the 'Hall of Health,' an exposition showing the basic facts of anatomy and physiology of man, the causes and prevention of disease and the conservation of health.

MASSACHUSETTS

Personal—Dr James J Minot was elected to fill the newly created position of honorary president of the Boston Tuberculosis Association at a recent meeting.

Society News—Dr John G Downing, Boston, discussed 'Dermatitis Venenata Due to Cosmetic and Industrial Irritants' before the Norfolk District Medical Society recently.—At a meeting of the New England Heart Association in Boston March 28 the speakers included Drs Mark D Altschule on 'Effect of Digitalis in Partial Heart Block' and Herrman L Blumgart on 'Cardiac Cirrhosis'.—At a meeting of the Boston Society of Anesthetists, March 15, Dr Gustave Philip Grabfield spoke on 'Clinical Thoughts on Pharmacology of Central Nervous System Depressants'.—The New England Society of Physical Medicine was addressed in Boston March 16 by Drs Heinrich G Brugsch and Joseph H Pratt on 'Indications and Contraindications of Ultra Short Wave Therapy'.—Dr Samuel H Epstein, among others, addressed the Boston Society of Psychiatry and Neurology March 17 on 'The Pathogenesis of Syphilitic Optic Atrophy'.—At a joint meeting of the Suffolk District Medical Society and the Obstetrical Society of Boston March 15, Dr James M Faulkner discussed 'Heart Disease in Pregnancy'.—Dr Chester M Jones addressed the South End Medical Club in Boston, March 15 on 'Diagnostic Aspects of Pain Referred from the Digestive Tract'.

MICHIGAN

Professor of History of Medicine—Dr Alfred O Lee, professor of modern languages, University of Michigan, Ann Arbor was recently appointed in addition professor of history of medicine by action of the board of regents according to the University Hospital Bulletin. This appointment is in the College of Literature, Science and the Arts and was granted to Dr Lee in recognition of the fact that his interest in medical history has led him to include instruction in this subject in his German courses for premedical students and in his course in the sociology of medicine, also given for premedical students. Dr Lee received his medical degree from the University of Heidelberg, Germany, but has never practiced medicine.

Personal—Dr David R Clark, Detroit has been made an honorary member of the Wayne County Medical Society.—Dr Joseph Stanley Leszynski, Detroit, has been appointed a member of the state board of registration in medicine succeeding Dr Frederick H Cole and Dr Francis J O'Donnell, Alpena to fill the unexpired term of Dr Elmer W Schnoor, Grand Rapids. Drs Eugene S Thornton, Muskegon, Harold L Morris, Detroit, and John J Walsh, Escanaba have been reappointed to serve as members of the board.—Dr William H Haughey, Battle Creek, was guest of honor at a dinner given by the Calhoun County Medical Society April 5 in recognition of his completion of fifty years of medical practice.

Society News—The Detroit Bar Association and the Wayne County Medical Society were addressed March 21 by Hon John V Brennan, judge of recorder's court of Detroit. Hon Harry S Toy, former attorney general of Michigan and former justice of the Michigan Supreme Court, Dr Lowell S Selling, director and Dr John A Larsen, assistant director psychopathic clinic, recorder's court the program was a symposium on the lie detector.—Dr Charles G Johnston, Detroit discussed intestinal obstruction before the St Clair County Medical Society March 1.—The Ironi Montcalm Counties Medical Society was addressed in Greenville March 8 by Drs Henry J Vandenberg and Charles F Ingersoll both of Grand Rapids on 'The Physician's Responsibility in Cancer and Practical Problems in X-Ray Therapy' respectively.—Dr William Wagner, Toronto addressed the Highland Park Physicians Club and the Wayne County Medical Society April 4 on 'The Pathogenesis of Anemia'. Dr Andrew R Riddell, Toronto addressed the medical section of the county medical society April 11 on 'Silico-sis and Its Relation to Tuberculosis and Other Fibrosing Lung Conditions'.

MINNESOTA

Graduate Courses in Obstetrics and Pediatrics—The second statewide graduate course in obstetrics and pediatrics will begin in Crookston and Winona May 8. The Minnesota State Medical Association, the University of Minnesota Medical School and the state department of health are cooperating in the courses, which are being financed by social security appropriations. Other centers where the lectures will be given are May 11, Hibbing and Willmar, May 18, Albert Lea and Fergus Falls, May 25, Worthington and Bemidji. The sessions in each center will last all day. There will be four lectures in obstetrics and four in pediatrics given by two obstetricians and two pediatricians. Complete information may be obtained from Mr. R. R. Rosell, executive secretary of the Minnesota State Medical Association, 11 West Summit Avenue, St. Paul.

Society News—Dr. Arvid Lindau, professor of general pathology and bacteriology, University of Lund, Sweden, gave the Mayo Foundation Lecture at the Mayo Clinic, Rochester, April 7 on "Nutritional and Gastrointestinal Diseases." Dr. William C. Gallic, Toronto, lectured April 14 on hernia, and Dr. Arthur W. Meyer, professor of human anatomy, Stanford University School of Medicine, April 25 on "Chronic Kinetic Lesions with Special Reference to Those in the Intervertebral Disks."—Dr. Frederick A. Willius, Rochester, will discuss "A Less Common Manifestation of Rheumatic Heart Disease" before the Hennepin County Medical Society in Minneapolis May 2. The society was addressed March 23 by Ancel Keys, Ph.D., Rochester, on "Diagnosis and Prognosis of the Normal Man"; it was addressed March 16 by Drs. Herbert M. N. Wynne, Minneapolis, on "Treatment of Second Stage Gonorrhea in Women" and Nora M. C. Winther, Minneapolis, on "Diagnosis and Treatment of Trichomonas Vaginalis."—Dr. Albert D. Ruedemann, Cleveland, discussed "Headaches of Ocular Origin" before the Minnesota Academy of Ophthalmology and Otolaryngology recently.

NEW JERSEY

Conference on Maternal and Child Health—The twentieth annual conference on maternal and child health under the auspices of the state department of health will be held in Elizabeth, May 5. Among the speakers will be Drs. George W. Kosmak, New York, on "Progress in Maternal Welfare in the United States"; Julius H. Hess, Chicago, "Progress in Child Health in the United States"; and Ira S. Wile, New York, "Mental Hygiene and the World Around the Child."

NEW YORK

State Medical Meeting—The one hundred and thirty-second annual meeting of the Medical Society of the State of New York will be held in New York at the Waldorf-Astoria May 9-12 under the presidency of Dr. Charles H. Goodrich, Brooklyn. Speakers at general sessions Tuesday and Thursday afternoons will be:

Mr. Victor E. Negus, London, "The Significance of Hoarseness";
Dr. Irvin Abell, Louisville, Ky., "President Elect of the American Medical Association: The Relation of Diabetes to Surgery";
Dr. Charles A. Gordon, Brooklyn, "Prevention of Maternal Deaths";
George R. Cowgill, Ph.D., New Haven, Conn., "Vitamins and the Clinician";
Dr. Frank H. Lahey, Boston, "Some of the Newer Surgical Entities of the Last Decade—Their Diagnosis and Management";
Dr. Louis A. Buie, Rochester, Minn., "The Physician's Responsibility in Preventive Proctology";
Dr. Edward A. Strecker, Philadelphia, "The Importance of Psychology in the Practice of Medicine";
Russell W. Bunting, D.D.S., Ann Arbor, Mich., "Diet and Dental Caries."

Among invited guests who will address the sections are:

Dr. Paul Titus, Pittsburgh, "Cesarean Section—Its Relation to Maternal Mortality";
Dr. Benjamin W. Carey, Jr., Boston, "Urinary Infections in Infants and Children—A Comparison of Therapeutic Methods";
Dr. Arthur J. Vorwald, Syracuse, N.Y., "Dust and Disease";
Dr. Raymond A. Vonderlehr, Washington, D.C., "Probabilities of a Disastrous Outcome in Treated and Untreated Syphilis";
Dr. Paul A. O'Leary, Rochester, Minn., "Significance of Asymptomatic Neurosyphilis";
Dr. Emmanuel Ross, Mintz, Boston, "Kidney Tumors—Some Causes of Poor End Results";
Dr. Royd R. Sayers, Washington, D.C., "Influence of Industrial Medical Work on General Health and Medical Science";
Philip Drinker, C.E., Boston, "Effects of Breathing the Products of Combustion from the Electric Arc";
Dr. Fremont A. Chandler, Chicago, "Surgery in Spastic Paralysis";
Dr. Paul C. Colonna, Oklahoma City, "A Reconstruction Operation for Old Ununited Fractures of the Femoral Neck."

New York City

Lecture by Dr. Hammarsten—Dr. Einar Hammarsten, professor of chemistry, Carolingian Medical University, Stockholm, Sweden, will deliver a lecture May 2 at the Rockefeller Foundation Theater under the auspices of the New York Medical College and Flower Hospital. His subject will be "The Duodenum and Its Associates, the Important Hormonal Centrum."

Cornell Alumni Day—The annual "Spring Day" of the Cornell University Medical College Alumni Association will be held at the college and New York Hospital May 5. During the day there will be a clinical program and the visiting alumni will be the guests of the board of governors of the hospital. At a banquet the speakers will be Edmund Lutz Day, Ph.D., president of Cornell, Mr. Austin H. MacCormick, commissioner of correction, and Dr. Benjamin J. Slater, medical director of the Eastman Kodak Company, Rochester.

Annual Meeting of Milbank Fund—The sixteenth annual conference of the Milbank Memorial Fund was held March 29-31 at the New York Academy of Medicine. Topics for discussion were new methods of testing for nutritional deficiencies and of appraising the state of nutrition, development of a program for eradication of tuberculosis, certain rural population problems, and the next steps to be taken in formation of a program for control of gonorrhea. Dr. Livingston Farrand, Brewster, N.Y., former president of Cornell University, was chairman of the conference, which was attended by more than 100 physicians and public health workers. Frank Porter Graham, D.Litt., president of the University of North Carolina, Chapel Hill, was the guest speaker at the annual dinner.

Society News—Speakers at a meeting of the New York Neurological Society with the section of neurology and psychiatry of the New York Academy of Medicine March 1 were: Drs. Israel S. Wechsler on "Ephephrine in Treatment of Convulsive Seizures"; I. I. Cohen, "Surgical Therapy in Certain Convulsive Disorders"; and Sander Lorand, "Perverse Tendencies and Fantasies—Their Influence on Personality."—Dr. Douglas Quick addressed the New York Roentgen Society, March 21, on cancer of the head and neck.—Dr. Madge T. Macklin, London, Ont., and Clara J. Lynch, Ph.D., addressed the New York Pathological Society at a joint meeting with the New York Gastroenterological Association March 29 on "Heredity in Cancer" and "Experimental Evidence on the Relation Between Heredity and External Factors in Cancer" respectively.

NORTH CAROLINA

State Medical Meeting at Pinehurst—The eighty-fifth annual session of the Medical Society of the State of North Carolina will be held at the Carolina Hotel, Pinehurst, May 2-4, under the presidency of Dr. Wingate M. Johnson, Winston-Salem. There will be general sessions Tuesday and Wednesday mornings. Among other speakers will be:

Dr. Edward A. Strecker, Philadelphia, "Functional Illness and the Medical Psychology Needed by the Practitioner in Its Treatment";
Dr. Charles Gordon Heyd, New York, "Clinical Essentials in Abdominal Diagnosis";
Dr. George M. Cooper, Raleigh, "A Statewide Program for a Maternity and Infancy Service";
Dr. Robert A. Ross, Durham, "Ovarian Cysts and Tumors";
Dr. Charles R. Bugg, Raleigh, "The Diphtheria Problem";
Dr. Walter J. Lackey, Tallston, "Function and Field of the Family Doctor";
Dr. Vance P. Peery, Kinston, "Endoscopy";
Dr. Julian M. Ruffin, Durham, "Amelior Dysentery in North Carolina";
Dr. Silas Raymond Thompson, Charlotte, "Mortality in Prostatic Surgery: Technique of Prostatic Resection."

Dr. Lester A. Wilson, Charleston, S.C., will be a guest of the section on gynecology and obstetrics speaking on "Late Puerperal Complications and Care." The North Carolina Public Health Association will hold its annual meeting May 2 with Dr. Wilson G. Smilie, New York, as the guest speaker at a dinner meeting on "Epidemiology of Acute Respiratory Infections."

OHIO

State Medical Meeting at Columbus—The ninety-second annual meeting of the Ohio State Medical Association will be held in Columbus May 11-12 under the presidency of Dr. John B. Alcorn, Columbus. Headquarters will be at the Neil Hotel. Guest speakers will be:

Dr. Fred Wise, New York, "Eczema and Its Treatment by the General Practitioner";
Dr. Clara M. Davis, Winnetka, Ill., "The Self Selection of Diet and Its Significance for Feeding in the Home";
Dr. Ferrin H. Long, Baltimore, "Observations upon Experimental Clinical Use of Sulfanilamide and Its Derivatives in the Treatment of Certain Infectious Diseases."

Dr Irvin Abell Louisville Ky President Elect of the American Medical Association Bilateral Renal Calculi
Dr Sumner L S Koch Chicago Infections of the Hand
Dr Hugo Roesler Philadelphia Hypertension
Dr Gabriel Tucker Philadelphia Cancer of the Larynx Diagnosis and Treatment with Observations on the Relationship of Benign Tumors of the Larynx to Cancer

A round table luncheon has been arranged by the section on public health and preventive medicine, to be held at the Deshler-Wallick Hotel Wednesday noon May 11, with Mr Leo F Ey, chief of the division of laboratories, state department of health, and Dr Warren C Breidenbach, Dayton, as speakers on "Newer Developments in Public Health Laboratory Service" and "Modern Therapeutic Methods in Pulmonary Tuberculosis Their Relation to the Public Health" The annual banquet will be held Thursday evening at the Neil House

Graduate Course in Toledo—Dr Wilhelm Dressler, Vienna, was the lecturer for the fourteenth graduate course offered by the Toledo Academy of Medicine April 26 29 on "Diseases of the Heart" The closing lecture was given at a general meeting of the academy on 'Pregnancy and Heart Disease Surgery and Heart Disease and Diagnosis and Treatment of Arrhythmias'

OKLAHOMA

Society News—The Garfield County Medical Society held a fracture symposium at Enid April 28 with Drs William B Carrell, Dallas Texas, and Earl D McBride, Oklahoma City, as guest speakers—Drs Hugh G Jeter and Joseph W Kelso, Oklahoma City, addressed the Pittsburg County Medical Society, McAlester, February 18, on 'Diagnosis of Cancer' and 'Ectopic Pregnancy' respectively

OREGON

Society News—Dr Richard B Cattell, Boston, addressed the Multnomah County Medical Society, Portland, March 16 on "Diagnosis and Treatment of Carcinoma of the Rectum and Colon" A symposium on scarlet fever was presented before the society, March 2, by Drs Ralph A Fenton London Howard Smith and Adolph Weinzierl, Portland—Dr Blair Holcomb Portland, addressed the Central Willamette Medical Society, Eugene, February 3, on 'Practical Endocrinology with Special Reference to Management of Obesity'—At a meeting of the Coos and Curry Counties Medical Society in Marshfield February 2 the topic of round table discussion was hemolytic and nonhemolytic streptococcus infections

Watch for Kidnaper Stevenson—Oregon physicians are asked by the Federal Bureau of Investigation to watch for one Clarence Vernon Stevenson, wanted for the kidnaping of Mary McElroy of Kansas City, Mo in 1933 It has been reported that Stevenson, who uses the names of Clarence Stevens, Clarence Stevenson, Henry F Nelson and Steve" has a heart ailment and it is believed that he will consult a physician According to the notice sent out by the bureau, Stevens disease is "thought to be leakage and enlargement of the heart He has also suffered from rheumatism for years Physicians consulted by Stevens or who have any information about him are asked to notify the headquarters of the Federal Bureau of Investigation in Portland, by telephone or telegraph, government rate collect The telephone number is Atwater 6171, local 544 Stevens is aged 30 years height 5 feet 7 inches, weight 145 medium slender build chestnut hair gray eyes medium complexion, American, born in Butler, Mo

PENNSYLVANIA

Society News—Dr Hugo Roesler, Philadelphia, addressed the Schuylkill County Medical Society at the Locust Mountain Hospital, Shenandoah, April 12 on 'Errors in Diagnosis and Treatment of Cardiovascular Disease'—Dr James R Johnston Pittsburgh addressed the Washington County Medical Society, Washington, April 13 on 'Office Gynecology'—Dr Charles Mazer, Philadelphia, addressed the Northampton County Medical Society April 15 on 'The Female Sex Hormones'

Committee on Psychiatric Service to Courts—On the authority of a resolution adopted at the annual meeting of the Medical Society of the State of Pennsylvania last October Dr Frederick I Bishop Scranton president of the society recently appointed a committee on psychiatric service The resolution recommended establishment of psychiatric services to assist the criminal courts of the commonwealth in the disposition of criminal offenders that adequate psychiatric service be established in all penal and correctional institutions in the

state and that every prisoner convicted of a felony be examined psychiatrically before he is paroled or commuted The committee, which was appointed to study ways of promoting these suggestions, consists of Drs Daniel J McCarthy, Philadelphia, chairman, Philip Q Roche, Philadelphia, Howard K Petr, Harrisburg, Horace V Pike, Danville, and George J Wright, Pittsburgh

Philadelphia

Potter Lecture at Jefferson—Dr William Boyd professor of pathology, University of Toronto Faculty of Medicine, delivered the William Potter Memorial Lecture at Jefferson Medical College April 18 on 'Growth, Normal and Abnormal'

Memorial to Dr Robinson—The trustees of the Philadelphia Institute for Medical Research unveiled a memorial tablet to the late Dr William Duffield Robinson April 7 at the institute's building at the Philadelphia General Hospital Dr Robinson who died in 1931, was active in the formation of the institute Dr Charles A E Codman, president of the board of trustees, presided and addresses were made by Drs Wilmer Krusen, Leonard G Rowntree and John D McLean

Pediatric Pharmacy Week—A committee of physicians and pharmacists is sponsoring the second annual Pediatric Pharmacy Week May 1-7 Pharmacists in Philadelphia and its vicinity are asked to use their window space during the week for displays designed to illustrate the importance of preventive medicine, particularly of modern immunologic procedures, in the reduction of disease and death among children Dr William N Bradley and Ambrose Hunsberger, Ph M, are chairmen of the committee Physician members are Drs Emily P Bacon, Harvey Evert Kendig, Wilmer Krusen, Julian M Lyon, Henry Harris Perlman and Ralph M Tyson

Society News—Dr James B Collip, Montreal, addressed the Philadelphia Pediatric Society, April 12, on "Anterior Pituitary Hormones"—A special meeting on tuberculosis was held by the Philadelphia County Medical Society April 20 with the following speakers Drs Frank W J Burge on 'Pneumoperitoneum Oxyperitoneum and Nitroperitoneum in the Treatment of Pulmonary and Abdominal Tuberculosis' William Devitt, Allenwood, Pa, "The New versus the Old in Tuberculosis Treatment," and Kendall Emerson, New York, "Five Points in the Tuberculosis Campaign"—Dr Everett I Evans, among others addressed the Physiological Society of Philadelphia April 18 on 'Diabetogenic Activity of the Anterior Pituitary'

Pittsburgh

Society News—Dr James H Rankin Jr, among others, addressed the Pittsburgh Neuropsychiatric Society March 21, at the Allegheny County Home and Hospital, Woodville, on 'Metrazol Treatment of Schizophrenia'—Speakers at a meeting of the Pittsburgh Academy of Medicine April 12 were Drs Charles F Kutscher on 'Retinal Arteriole Changes Significant of Hypertension', Adolphus Koenig, 'Photoelectric Cardiograms and Their Teaching Value" and Everett M Baker, 'Use of Peritoneal Drainage in Abdominal Operations'

SOUTH DAKOTA

State Medical Meeting at Huron—The fifty-seventh annual session of the South Dakota State Medical Association will be held at the Marvin Hughtt Hotel, Huron May 9-11 The morning sessions will be devoted to clinics conducted by guests In the afternoons addresses will be presented by the following speakers

Dr Henry E Michelson Minneapolis Dermatologic Diagnosis for the General Practitioner
Dr Charles Wilbur Rucker Rochester Minn The Relation of Tears to Some Common Eye Diseases
Dr Walter A Fansler Minneapolis Diagnosis and Office Treatment of Rectal Diseases
Dr Virgil S Counsellor Rochester The Uterus as a Surgical Problem in General Practice
H M Sweeney Ph D Vermilion The Physiology of Hypertension
Dr Charles G Sutherland Rochester Minn The Value of the X Rays in Diagnosis
Dr Henry F Helmholtz Rochester Recent Advances in the Treatment of Urinary Infections in Childhood
Dr Solon Mary White Minneapolis title to be announced
Dr Everett D Phillips Iowa City Obstetric Syphilis
Dr William W Bauer Chicago The Doctor in Health Education

The annual banquet will be held Tuesday evening May 10 with Dr Bauer as the speaker on 'Popular Beliefs That Are Not So' The South Dakota Academy of Ophthalmology and Otolaryngology will meet in the morning on May 10 with the following speakers Drs James D Alway Aberdeen on 'Foreign Proteins in Eye Therapy' George M Constans, Bismarck N D 'Management of Squint' Laurence R Boies Minneapolis 'Modern Uses of Endoscopic Procedures' and Charles W Rucker Rochester 'The Visual Pathways'

TEXAS

State Medical Meeting in Galveston—The seventy-second annual session of the Texas State Medical Association will be held in Galveston May 10-12, with headquarters at the Hotel Galvez. Dr. Calvin R. Hannah, Dallas, is president. Guest speakers who will address general sessions are:

Dr. John H. J. Upham, Columbus, Ohio, President of the American Medical Association, Modern Problems of Medical Practice
Dr. Reed M. Nesbit, Ann Arbor, Mich., The Place of Transurethral Resection in Prostatic Surgery
Dr. Wendell G. Scott, St. Louis, Diagnosis of Thoracic Diseases Other Than Tuberculosis
Dr. Robert A. Strong, New Orleans, Preventive Pediatrics
Dr. Edwin E. Osgood, Portland, Ore., Differential Diagnosis and Treatment of Anemias
Dr. Waltham Walters, Rochester, Minn., Earlier Recognition of Intra-Abdominal Malignant Lesions
Dr. Emil Novak, Baltimore, Cause and Treatment of Functional Uterine Bleeding
Dr. John A. Kolmer, Philadelphia, Syphilis
Dr. John J. Shea, Memphis, Tenn., Problems of the Deaf
Dr. Arthur T. McCormack, Louisville, Ky., Whose Responsibility Is Public Health and Medical Service?

The guests will also address section meetings and several special combined section meetings, a new feature this year, as well as luncheon meetings. Dr. Ralph M. Waters, Madison, Wis., who will be the guest of the Texas Association of Medical Anesthetists, will address the section on surgery on "A Study of Morphine, Scopolamine and Atropine and Their Relation to Preoperative Medication and Pain Relief." Other special societies that will hold their annual meetings at this time are the Texas Railway Surgeons Association, Texas Neurological Society, Texas Dermatological Society, Texas State Heart Association and the Conference of State and County Health Officers. The Woman's Auxiliary will hold its meeting at the Buccaneer Hotel.

VIRGINIA

Venereal Disease Control Officer—Dr. Francis W. Upshur, Richmond, has been appointed to direct a program for the control of venereal disease in that city. The city council has appropriated \$4,000 and the local chapter of the American Red Cross \$2,000 to finance the work. Dr. Upshur, a graduate of the Medical College of Virginia, was at one time in charge of venereal disease wards in the U. S. Marine Hospital, Boston, and during the World War in charge of the division of venereal disease and diseases of the skin at the Norfolk Naval Hospital.

WASHINGTON

Plague Infection in Adams County—According to *Public Health Reports*, plague infection has been proved in pools of fleas and lice collected from rodents in Adams County as follows: March 7 in a pool of 181 fleas from nineteen *Citellus townsendii* shot two miles east of Lind and in a pool of 103 lice collected from the same group of ground squirrels; March 9 in a pool of 179 fleas collected from twenty-seven *Citellus townsendii*, shot one mile southeast of Lind.

WEST VIRGINIA

Society News—Drs. Randolph L. Anderson and Harry E. Baldock, Charleston, addressed the Logan County Medical Society, Logan, March 9 on "Chronic Arthritis" and "Meningococcus Meningitis" respectively. Dr. Harry T. Schiefelbern, Welch, discussed otitis media at a meeting of the McDowell County Medical Society, Welch, March 9. Dr. William B. Porter, Richmond, Va., addressed the Cabell County Medical Society, Huntington, March 10, on "The Heart and Physiologic Adjustments in Chronic Anemia." At a meeting of the Central West Virginia Medical Society in Sutton, March 19, the speakers were Drs. Theresa O. Snaith, Weston, on care and feeding of infants; John E. Cannaday, Charleston, diagnosis and treatment of malignant conditions of the large bowel; and Howard A. Swart, Charleston, new methods of treating fractures. Dr. Louis H. Douglas, Baltimore, addressed the Eastern Panhandle Medical Society in Charles Town, March 9, on maternal mortality. Drs. John Bankhead Banks and Pat A. Tuckwiler, Charleston, addressed the Greenbrier Valley Medical Society, Lewisburg, recently, on "Proctology: Diagnosis and Treatment of Certain Rectal Conditions of Sacral Anesthesia" and "Methods of Diagnosis and Treatment of Allergy" respectively. Dr. Herbert H. Haynes, Clarksburg, addressed the Lewis County Medical Society, Weston, March 8, on carcinoma of the rectum.

GENERAL

Unauthorized Magazine Salesman—The circulation department of *Newsweek* reports that a man named C. Q. Reed, who is no longer an authorized representative of the magazine, is continuing to sell subscriptions, especially to physicians. He does not turn in either the money received or the subscriptions. The magazine announces that it will honor any receipts held by physicians on orders they have given to Reed and on which they have not received service if they will send in the receipts and statements of the amount of money paid to the salesman.

Tenth Pan American Sanitary Conference—Surgeon General (Ret.) Hugh S. Cumming, director of the Pan American Sanitary Bureau, Washington, D. C., announces that the tenth Pan American Sanitary Conference will be held in Bogota, Colombia, September 4-18. Subjects to be discussed include organization of a Pan American campaign against venereal disease, social security in its medical and public health aspects, control and prevention of yellow fever, recent achievements in the study of leprosy and the campaign against the disease, campaigns against tuberculosis, diseases produced by viruses and the problem of germ and virus carriers in epidemiology. The last previous conference was in Buenos Aires in 1934.

Guggenheim Fellowships Awarded—The fourteenth series of annual fellowship awards of the John Simon Guggenheim Memorial Foundation includes the following:

Dr. Henry N. Harkins, instructor in surgery, University of Chicago, for a study of the causes and nature of traumatic shock.
Clyde E. Keeler, Sc.D., instructor in ophthalmic research, Harvard University Medical School, for collection of material for a book on genetics in relation to medicine.
Dr. Sydney William Britton, professor of physiology, University of Virginia, Department of Medicine, Charlottesville, investigations of the function of the adrenal cortex and the kidney in primitive mammalian forms and in some of the primates.
Alfred George Marshak, Brookline, Mass., investigations of the nature of chromosome division, especially the nature of chromosome structure as revealed by response to treatment with x-rays and with neutrons.

The stipends are about \$2,500 a year.

Report of Impostor—A man who said he was Dr. A. B. Morris of Gainesville, Ga., recently appeared in Joplin, Mo., announcing that he planned to locate there as his office and equipment had been destroyed by a storm. He also claimed to have had an automobile accident near Hot Springs National Park, Ark., where he had been in a hospital for some time. He then attempted to borrow money from Joplin citizens to last him until he received money from elsewhere. Inquiry directed to Gainesville and search of the American Medical Directory revealed no person of the name A. B. Morris. The state medical board of Georgia also reported that A. B. Morris was not licensed as a physician in Georgia. According to Joplin authorities, files of the Masonic order record a "Dr. Andrew W. Morris" of Gainesville, Texas, who attempted to obtain money in Syracuse, N. Y., in 1934. At that time he stated that he was a laboratory technician in the Eastman Kodak Company laboratories and showed a medical license from Indiana. He was said to be 70 years old. The man reported from Joplin appeared to be about 60 but intimated that he was 70 or older. He was 5 feet 6 inches tall, weighed about 165 pounds, was clean shaven, had black hair and carried a cane. He spoke English with an accent German and Yiddish and claimed also to know French, Italian, Rumanian and Greek.

Congress of Physicians in Atlantic City—The Congress of American Physicians and Surgeons, which meets every five years, will be held at Haddon Hall in Atlantic City, May 3-4, under the presidency of Dr. James B. Herrick, Chicago. There will be two sessions of the congress, one Tuesday evening, May 3, at which Dr. Herrick will deliver an address, and a scientific session Wednesday afternoon. Speakers at this meeting will be:

Drs. Willard B. Soper, New Haven, Conn., and James Burns, Amherst, N. Y., New York, Pulmonary Tuberculosis Among Young Adults, Particularly Among Those Professionally Exposed to the Disease.
Dr. William C. Quinby, Boston, Urinary Stone, Some Recent Developments.
Dr. Tracy J. Putnam, Boston, Modern Forms of Treatment of Disease of Nervous System.
Dr. Dallas B. Phemister, Chicago, Variation in the Cholesterol Excretion and Calcium Carbonate Content of Gallstones.

Meeting as a part of the congress will be several special societies including the following:

The American Surgical Association will meet at the Traymore, May 2-4. A feature of its program will be a conference on treatment of infections presented by Dr. John S. Lusk, Wood, Philadelphia; Champ Lyons, and Richard H. White,

Boston, Alexander Randall and Patrick Boland Hughes, Philadelphia, Perrin H Long and Eleanor A Bliss, Sc D, Baltimore

The American Neurological Association will meet at the Ambassador May 2-4 Dr Charles A Elsberg, New York, president of the association, will give the Charles K. Mills Memorial Lecture Monday evening May 2 on 'Cerebral Activity Including Conscious Sensation as a Physicochemical Process'

The Association of American Physicians will hold its fifty-third annual meeting at Chalfonte-Haddon Hall May 3-5

The fourteenth annual meeting of the American Association of the History of Medicine at the Hotel Chalfonte, May 2, will commemorate the two hundredth anniversary of the death of Herman Boerhaave, "supreme clinician of the eighteenth century"

The sixtieth annual congress of the American Laryngological Association will be held at the Marlborough Blenheim, May 2-4

The American Association of Pathologists and Bacteriologists will convene for its thirty-eighth annual session at the Chalfonte Haddon Hall May 3-4

A symposium on display methods in medical museums will be a feature of the thirty-first annual meeting of the International Association of Medical Museums at the Chalfonte-Haddon Hall May 2 The American Association for Cancer Research will hold its thirty-first annual session at the Chalfonte Haddon Hall May 2

CANADA

Personal—Dr Seraphin Boucher has retired as director of the department of health of Montreal after twenty-five years' service He has been succeeded by Dr Adelard Groulx, Montreal—Dr Gregoire F Amyot Vancouver assistant provincial health officer of British Columbia, has received leave of absence for two years to undertake an extensive survey of state health administration in association with Carl Buck Dr P H, field director of the American Public Health Association

University News—Elmer V McCollum Ph D, Baltimore recently delivered the Gordon Bell Memorial Lecture at the University of Manitoba Winnipeg at a special convocation The university conferred on Dr McCollum the honorary degree of doctor of laws honoris causa—High voltage x-ray therapy apparatus has been installed at the Winnipeg General Hospital in a new building especially constructed for this and the other x ray equipment already in the hospital The new equipment was made possible by a gift from Mr John A Torlong as a memorial to his wife

CORRECTION

Nonoperative Management of Remaining Common Duct Stones—In the paper with the foregoing title by Best and Hicken in THE JOURNAL, April 16, the authors desire to add to the legend of figure 1 that *A* represents the control period, *B* the period following administration of dehydrocholic acid by mouth for several days and *C* the period following the intravenous injection of 10 cc of a 20 per cent solution of sodium dehydrocholate

Government Services

Examination for the Army Medical Corps

The War Department has announced an examination for the purpose of qualifying candidates for appointment as first lieutenants in the Medical Corps Regular Army, to fill vacancies occurring during the fiscal year 1939 The examination will be conducted July 18-22 both dates inclusive by boards convened throughout the United States It will consist of a physical examination a written examination in professional subjects and a determination of the candidates' adaptability for military service Licentiates of the National Board of Medical Examiners may be exempted from the written professional examination The examination is open to all male graduates of acceptable medical schools who have completed one year's internship in an approved hospital and who will not be over 32 years of age at the time it will be possible to tender a commission Full information and application blanks will be furnished on request addressed to the Adjutant General War Department Washington D C Applications will not be considered after July 2

Foreign Letters

LONDON

(From Our Regular Correspondent)

April 2, 1938

A New System of Nerves

Sir Thomas Lewis has reported from the Clinical Research Unit of University College Hospital to the Medical Research Council observations on cutaneous hyperalgesia that have led to the discovery of a new system of nerves It has been observed that a widespread and lasting area of hyperalgesia appears in many subjects around a point of faradic stimulation or tiny crush of the skin It has been shown that this is independent of the central nervous system and arises out of changes in the region of the injury and through a local nerve mechanism Impulses traveling through these local nerves set up a process in the surrounding skin of a relatively stable kind and one which is independent of the original injury Similar hyperalgesia may be produced also by stimulating cutaneous nerve trunks, this effect appearing in the area of cutaneous distribution of the nerve is not prevented by previously blocking the nerve proximal to the point stimulated but is prevented by a block distal to the point If the mucous membrane of the maxillary antrum is stimulated hyperalgesia develops over the whole area supplied by the maxillary division of the fifth nerve, reproducing the superficial tenderness that often follows antral catarrh By stimulating the digital nerve to the radial side of the little finger, similar hyperalgesia can be produced in the whole area of skin supplied by the ulnar nerve All the instances of hyperalgesia described are produced through the same local nerves and the same effector mechanism Evidence has been brought forward to show that the nerves concerned are arranged as arborizations of axons in the skin and that they belong neither to the sensory nor to the sympathetic system

The newly discovered system of nerves has been named 'nocifensor' because they appear to be specially concerned in local reactions of defense, exemplified by the hyperalgesia and probably also by the well known vascular flare which surrounds injuries of the skin The observations illustrate how responses that are part and parcel of the inflammatory reaction may be set up distally in the skin through nerve channels The effects of asphyxia and of cocaine on the hyperalgesic reaction confirm the view that the fibers concerned belong to a special system and not to the sensory system

With Dr Proclin Sir Thomas Lewis has completed a research on sensory response to painful stimuli A needle prick or a transient application of heat awakens from the finger a double pain response The first response travels in fibers of fast conduction and is readily obstructed by local asphyxia the second travels in fibers of slow conduction and is readily obstructed by using cocaine The interval between the two responses increases as the stimulus is moved peripherally and becomes large when a stimulus is applied to the toe The delay of the second response is in the somatic nerves and not in the spinal cord These observations fall into line with those previously made by Gasser, who showed that afferent impulses pass from the periphery in nerves of very different conduction rates They are of particular interest in showing that pain impulses pass by both fast and slow conducting fibers They are relevant to the delay of prick response in tabes dorsalis and preliminary observation by Dr Proclin suggest that in this disease, slow conducting fibers are relatively unaffected

Thrombosis of Peripheral Veins a Sign of Visceral Cancer

In the Birmingham Medical Review Dr A P Thomson has called attention to a clinical fact first described by Trousseau in 1862 but almost completely overlooked in modern practice—

spontaneous thrombosis in both the upper and the lower limbs as a valuable sign in the diagnosis of visceral cancer. Trousseau pointed out its value in cases of cancer of the stomach not accessible to the usual methods of investigation. Dr Thomson reports three cases. A healthy married woman, in the early forties, after a few weeks of ill health had thrombosis of a vein of the right leg. There was slight edema, which subsided under rest in bed, but almost immediately after she was allowed to get up she had a similar thrombosis in the other leg. A month later there was a similar thrombosis in the right thigh. Her general condition was good and physical examination was negative. As she had lost appetite and a little weight, an x-ray examination of the alimentary canal was made and was reported negative. Although there was no fever, Dr Thomson suggested the possibility of thrombophlebitis migrans and search was made for foci of infection. Several teeth were condemned and removed, the tonsils were removed, and the sinuses were washed. A vaccine was prepared from the root of a tooth. But the patient continued to deteriorate and had several more attacks and one attack of pleurisy with hemoptysis, attributed to thrombosis of the pulmonary veins. Fourteen months after the original thrombosis she died with obvious evidence of malignant disease of the liver. The site of the primary cancer was never determined.

A man in the early fifties, admitted to the General Hospital, Birmingham, in 1936, was slightly anemic, had lost appetite for four months and had vague abdominal distress after meals. Before admission he had two attacks of thrombosis in the veins of the legs. X-ray examination showed a deformity of the cardiac end of the stomach. Further attacks of venous thrombosis occurred, and he died a few months later with evidence of metastases in the liver.

A man of 52, a total abstainer, who had never had any illness, began to complain of ill health. His appetite failed and he lost a few pounds. Later he had vague discomfort in the right iliac fossa and afterward in the right hypochondrium. X-ray examination was negative. In July, from six to eight weeks after he first consulted his doctor, he had a stab of pain in the right calf. There was a patch of phlebitis. August 26 he had pleurisy at the right base. Though physical examination was completely negative when he was seen a few days later by Dr Thomson, visceral cancer was suggested in view of the spontaneous thrombosis and cachexia. Later another patch of phlebitis occurred, this time in the left leg. Physical examination was still negative, but frequent attacks of venous thrombosis of the leg followed. September 27 the liver was hard. Further attacks of thrombosis occurred and on October 25 laparotomy was performed and revealed carcinoma of the tail of the pancreas with metastases in the liver.

The pathology of the thrombosis remains obscure. Trousseau showed that it was not due to pressure. It does not seem to be due to infection as in none of these cases was it associated with any fever. There was no evidence of implantation of malignant cells in the wall of the vein. Dr Thomson suggests that the most probable cause is some chemical change in the blood following the development of cancer.

The Prevention of Explosions in Operating Rooms

The National Physical Laboratory has investigated the question of explosions in operating rooms through the accidental formation of electric sparks, which has been suggested as an explanation of some of these accidents. The laboratory has found that it may be possible by the movements of blankets and other objects to produce sparks capable of igniting anesthetic vapors. As a result of the investigation recommendations have been made which should minimize the risk. These include the provision of earthing chains trailing from operating tables on to a semiconducting floor and the use of the partially conducting rubber which is now available.

The Protection of X-Ray and Radium Workers

To prevent injuries to x-ray and radium workers the British X-Ray and Radium Protection Committee was formed in 1931 as the result of cooperative action between the Royal Society of Medicine, the Röntgen Society, the British Association for the Advancement of Radiology and Physiotherapy, the Institute of Physics, the Radium Institute and the National Physical Laboratory. The committee has issued from time to time recommendations, of which the fifth has just been published. The problem of protection for x-ray workers has been eased by the introduction of the self-protected tube and more recently by the shock-proof tube equipment. The available evidence suggests that under satisfactory working conditions a person in normal health can tolerate with impunity exposure to x-rays and radium gamma rays of about one roentgen per week. The following protective measures are recommended.

WORKING HOURS AND OTHER CONDITIONS

Not more than seven working hours a day. Whole-time workers should not be called on for other hospital service. No more than five working days a week, the off days to be spent as much as possible outdoors. Not less than four weeks holiday annually, preferably consecutive. No person to be employed whose blood or general health is unsatisfactory. The amount of radiation received by operators should be systematically checked to ensure that the tolerance dose is not exceeded. Before beginning work the normal leukocyte level should be found by making three total and differential counts in the afternoon. If no total count exceeds 6,000 and no lymphocyte count reaches 1,200 the applicant should not be accepted. Periodic counts should be made every six months in the case of the x-ray worker and every three months in the case of the radium worker. If at any time a decided and sustained drop in total leukocyte or total lymphocyte count is found, work should be stopped and treatment undertaken.

GENERAL RECOMMENDATIONS

X-ray and radium departments should not be below the ground level. Damp rooms should be avoided. All rooms, including photographic dark rooms, should be provided with windows affording good lighting and ventilation. They should preferably be decorated in light colors. A working temperature of 18 to 21°C (64.4 to 69.8°F) is desirable in x-ray rooms, which should be large enough for convenient layout of equipment. X-ray generating apparatus employing mechanical rectifiers should preferably be in a separate room from the x-ray tube. An operator should on no account expose himself to direct x-ray beams (valve tubes used improperly may produce x-rays). The tube should be self-protected or surrounded with protective material. In diagnostic work with other than completely protected tubes, the operator should be protected from stray radiation by a screen of minimum lead equivalent of 1 mm. All fluoroscopic examinations should be conducted as rapidly as possible with minimum intensities and apertures, and all collimators and stands should be provided with arrangements for protecting the operator against scattered radiation from the patient. Protective gloves should have a value not less than 0.33 mm of lead and aprons of 0.5 mm. In treatment the operator should be outside the x-ray room behind a protective wall.

PROTECTION FROM RADIUM

To protect the hands, radium should be manipulated with long-handled forceps. All manipulations should be as far as possible. The radium safe should be as distant as possible from the personnel and provided with individual protection. To protect the body from the gamma rays, a lead handling screen of not less than 25 cm of lead should be used. The risks in using large quantities of radium in therapy may be largely obviated by some form of remote control in which the radium is introduced into the container and the latter has been adjusted on the patient.

Protest Against Sale of Sulfanilamide
Over the Counter

A letter to the editor of the *Siecle medical* by Prof. Jules Janet, an authority on gonorrhea, appears in the April 1 issue of that journal. The indiscriminate sale by druggists directly to patients of sulfanilamide and similar preparations ought to be stopped. Some experiences in his practice were cited by Professor Janet to show that these newer drugs should be employed only under medical supervision. He had prescribed from six to eight tablets each containing 0.5 Gm ($7\frac{1}{2}$ grains) in nine cases. This was the dose recommended by the pharmaceutical houses. In these nine cases of gonorrhea he had observed a hematuria of renal origin, a generalized icterus and a multiple neuritis of the arm and thorax, the last named of three days' duration. Even when the dose was reduced to four tablets a day, a hematuria of renal origin was noted in the same patient who presented this symptom with the larger dose. The dose was then reduced to two tablets a day in three cases. One of the three patients, a young man with an anterior urethritis, had been given local treatment (permanganate irrigations) and two tablets of sulfanilamide (0.5 Gm) daily. About thirty-six hours later he appeared pale and complained of a headache. The next day, the lips and nails were cyanotic. All these symptoms followed the use of only four tablets a day, or a total of 2 Gm of the drug, and disappeared as soon as its use was discontinued.

Present Status of Chemotherapy of Gonorrhea

A meeting was held at the request of the minister of public health March 21 to evaluate the use of sulfanilamide and similar preparations in the treatment of gonorrhea. A report of this meeting by Prof. Constantin Levaditi of the Institut Pasteur appeared in the April 1 issue of the *Siecle medical*. The most prominent venereologists of France took part in the discussion. The hope of a specific remedy to combat gonorrhea has not been fulfilled. The risk of serious complications following the use of the newer preparations is not to be overlooked. To have an effect on the gonococcus, the drugs must be given in such large doses as to risk the occurrence of serious systemic complications. The result is that, in order to avoid such sequelae the drugs must be given in such relatively small doses as to lose all their action on the gonococcus in the majority of cases. Most of those who took part in the discussion were of the opinion that, confronted with the alternative of giving sufficiently large doses to have an actual effect on the gonococcus or to fall back on the older methods of local treatment, the latter would still remain the method of choice. Chemotherapy must be regarded as of value when associated with local treatment but should not be depended on as the sole method. As such an adjuvant treatment, the newer preparations were of especial value in gonorrhea in the female and in epididymitis, provided the drugs were given in not too large doses and only under constant medical supervision. No matter which of the newer specific drugs were used there had been a recurrence in 30 per cent of the cases.

To avoid the use of these newer drugs without daily medical supervision, it was the sentiment of the meeting that they should be placed in the narcotics list, i. e., to be sold by druggists only when prescribed by physicians.

Agranulocytosis During Attack of Cholecystitis

A case of agranulocytosis during an attack of cholecystitis was reported by Dr. Pasteur Vallery-Radot and his associates at the January 28 meeting of the Societe medicale des hopitaux. A woman aged 26 was admitted May 2, 1935, because of a severe ulceromembranous pharyngitis. Smears revealed the presence of numerous spirilla, and only staphylococci were found

in cultures. There was marked tenderness over the gallbladder region. The blood examination showed 2,000 leukocytes per cubic millimeter associated with absence of polymorphonuclear leukocytes. There was a history of recurrent attacks of cholecystitis. The temperature was 104 F and the patient appeared extremely ill. The number of leukocytes dropped to 1,200 per cubic millimeter and rose to nearly 12,000 with 68 per cent polymorphonuclears only when the membranes in the buccopharyngeal region began to disappear, about two weeks after admission to the hospital. Similar cases of agranulocytosis during an attack of cholecystitis have been reported by Peritz and also by Sabrazes and his associates.

"Atrophy" of Liver Following Injection
of Antitetanus Serum

At the January 28 meeting of the Societe medicale des hopitaux, Dr. Jacques Caroli reported a case of severe icterus and acute hepatic atrophy following prophylactic injection of 10 cc of antitetanus serum, ten days before admission to the hospital. The chief prodromal symptom was an intense headache, which receded as soon as the icterus became manifest. The icterus, which at first gave the impression of being of a mild catarrhal type, was accompanied on the eighth day by bleeding from the gums, severe epigastric pain and diarrhea. The coagulation time was twenty-one minutes, but the bleeding time was normal. The stools contained blood and traces of bilirubin. Cholecystostomy was followed by a marked improvement of the clinical picture. Biopsy specimens of the liver tissue taken at the time of operation revealed a condition which the author terms "acute gray atrophy." The parenchyma failed to show any trace of bile pigments and red blood cells, a condition which could be best explained as being the result of anaphylactic edema complicated by necrosis of the central portion of the lobules.

Basal Metabolism in Children with Goiter

A careful investigation on the basal metabolism in children with goiter was presented in a paper by Drs. Mouriquand and Enselme at the March 15 meeting of the Academie de medecine. In fifty children with goiter, of whom forty-three were girls, the metabolism was normal in seventeen, increased in twenty and decreased in thirteen. Of those showing increased metabolism, five had a basal metabolism of less than plus 10, probably of emotional origin, and nine of less than plus 20, which might be ascribed to hypersympathicotonia. In six children the metabolism rate varied from plus 21 to plus 70. In thirteen of the fifty children there was a lowered rate varying from minus 10 to minus 30. These children presented the classic signs of hypothyroidism in the form of pallor, retarded intellect and puffiness of the face.

BERLIN

(From Our Regular Correspondent)

March 7, 1938

Mortality in the Berlin Hospitals

Dr. Conti, Berlin municipal medical counselor, in the *Aerzteblatt für Berlin* has pointed out that the number of deaths in Berlin's municipal hospitals is disproportionately great. Investigation has proved that doctors are hospitalizing a mounting number of incurably ill patients. This trend may be explained in part as due to the aging of the population, to bad living conditions and to the fact that since the abolition of unemployment a sick person's relatives have no time to take care of him. Moreover it cannot be denied that hospitalization may be a means of evading personal responsibility, in fact, this motivation is often obvious. This trend exerts a deleterious influence on all hospital patients and the expenses entailed by the care of so many hopeless cases makes hospitalization more costly for patients whose prospects for cure are favorable. Dr. Conti feels that a practitioner, whenever

38

ST. BACCUS MEDICAL COLLEGE
S. M. C. Medical College

possible, should keep the patient at home if no favorable result is to be expected from hospitalization

Tuberculosis in the Schools

Tuberculosis in the schools was recently the subject of an article by Dr Denker and Dr Seifert in the *Reichs-Gesundheitsblatt*. Legislation designed to mitigate the danger of infection among teachers and pupils has been enacted in Germany. By the terms of one such ordinance a teacher or pupil afflicted with infectious tuberculosis is forbidden to enter a schoolroom. Since 1934 a special law has been in force in Prussia, by the terms of which all cases of tuberculosis, fatal or otherwise, must be reported to the authorities. This applies to the disease in all its forms. Even a well founded suspicion that a person is afflicted with tuberculosis of the skin should be communicated to health officials. All persons preparing themselves for teaching, candidates for teaching positions and young teachers must submit an official medical certificate of good health wherein the condition of the lungs must have been verified by a roentgen examination. Legislation subsequently enacted contains provisions for special observation of tuberculous children.

Control of tuberculosis is an official duty of public health officers, particularly the detection of cases. Group examinations have become a part of the school medical service. The search for tuberculosis in school children is carried on with the aid of the tuberculin test. If a certain class has an exceptionally high incidence of positive reactions it is assumed that a source of infection exists within the class, and both pupils and teacher are submitted to roentgen examination. Children with positive tuberculin reactions have tended to decrease in number in the course of the years. Pirquet in his time elicited positive reactions in about 100 per cent of school children in Vienna. Today the proportion is 40 per cent or less. Now if more than 40 per cent of the children in a certain class show positive reactions the teacher probably is actively tuberculous. Children whose reactions are positive are next thoroughly examined clinically to ascertain whether active tuberculosis is present. The National Antituberculosis Commission has formulated the following classifications of conditions presented by children whose tuberculin reactions are positive: (1) infectious tuberculosis requiring treatment, (2) noninfectious tuberculosis requiring treatment, (3) tuberculosis requiring observation, (4) inactive tuberculosis, observation not required. Observation has taught that mortality from tuberculosis is higher among children who previously have exhibited positive reactions to the tuberculin test than among children whose reactions were previously negative.

A Study of Spermatozoa

Strasy and Generales of Berlin contributed to the annual convention of the German Genetic Society a study of the spermatozoa in healthy and in congenitally diseased men. The principal observation was the lack of uniform spermatozoa. The ratio of normal to modified spermatozoa varies, the average ratio being 81:19 in a healthy, procreative man and 37:15:62:85 in a man with hereditary disease. Among schizophrenic men, for example, the ratio is 46:2:53:8, among congenitally feebleminded men 38:2:61:8, among chronic alcohol addicts 24:9:75:1. According to this report, which will require further verification, two questions remain unanswered. To what degree is the spermatozoal picture influenced by the actual genotype? and Is there any correspondence between the spermatozoal picture and particular hereditary diseases?

The Behavior of Mandelic Acid

Prof F Wrede physiologic chemist of Kiel has investigated the behavior of mandelic acid within the human and animal organisms. Wrede observed that only about 70 per cent of racemic mandelic acid was eliminated in the urine. Recalling the work done by O Neubauer H Fischer Dudley

and Dakin, Wrede sought to determine whether benzoyl-formic acid is capable of producing mandelic acid while in transit through the organism. No racemic mandelic acid could be detected in the urine of human subjects or of dogs which had ingested benzoyl-formic acid. It is obvious, however, that man and dog react differently to this substance.

Wrede's observations are at variance with those of O Neubauer, who on the basis of analytic studies of phenylacetic acid had established two cardinal principles that of oxidative deamination and that of optically active reduction. A more critical attitude must now be brought to bear on these principles.

Tuberculosis in Germany

The mortality from tuberculosis in Germany is gradually decreasing. Figures recently issued by the National Health Bureau show that the rate from 1892 to 1894 was still 225 deaths of tuberculosis per 10,000 of population, in 1934 the corresponding rate was only 72. Complete figures are not yet available for 1935. Variations in the mortality from tuberculosis in urban as contrasted with rural regions are not great. The incidence of tuberculous meningitis, a disease of childhood is influenced by the size of the child population of a certain region. The larger cities belong among the communities reporting higher mortality from tuberculosis of the respiratory system. This is due in part to the migration of large numbers of persons of the intermediate age groups to the cities. In 1934 the mortality from tuberculosis in cities of more than 100,000 was 72 per 10,000 of population, in smaller communities the rate was generally less, dwindling to a minimal 60 in towns of 15,000 population. The average rate for all these urban communities was 69. No corresponding statistics are available for the distinctly rural regions. Since, however, the mortality from tuberculosis in the entire reich was 72 per 10,000 of population, namely, greater than the average of all urban communities, it may be inferred that the mortality is higher in the rural than in the urban communities.

The mortality from tuberculosis is higher among the male than among the female population. In 1934 the rate for the male sex was 78, for the female sex 66 per 10,000. The male death rate was thus 118 per cent that of the female. This excessive male susceptibility to fatal tuberculosis was not present at all age levels. Between the ages of 5 and 30 years the death rate was greater among females than among males. Whereas the mortality of male nurslings was 123 per cent that of female nurslings, among persons between the ages of 15 and 30 the male mortality from tuberculosis was only 83 per cent of the female mortality. For men of the age group 30-45, however, the death rate was 129 per cent that of women in the same group. Among persons between the ages of 45 and 60, nearly twice as many men as women died of tuberculosis. The highest male mortality from the disease was among men from 60 to 70 (125 per 10,000), the highest corresponding female rate was in young women aged from 15 to 30 (90 per 10,000). Nearly 40 per cent of deaths of women in the latter age group were caused by tuberculosis.

Tularemia in Germany

According to a report issued by the National Health Bureau the first investigations of tularemia among game animals was undertaken during the hunting season of 1930-1931. Simultaneously investigations were begun to discover possible unrecognized cases in man. In March 1931 a case of tularemia was reported in an employee of an institute of venery who apparently had become infected in 1928 while dissecting game animals. This case and a second subsequently reported were both of the ulceroglandular type, which is acquired only by direct contact with diseased animals. The first case (1936) of tularemia in which the diagnosis was confirmed by culture of the causative agent was of the oculoglandular type. The contagion had been transmitted by insects. Occult enzootic foci of contagion seem to be present in small game but autogenous tularemia is not

domesticated hares, rabbits and so on was not observed. In the German reich at present tularemia is not serious, but this condition could be quickly changed by the spread of contagion from nearby Austria and Czechoslovakia. Studies made in collaboration with the Swedish Institute of Bacteriology at Stockholm have demonstrated that the serobacteriologic identity of the pathogenic organisms may be differentiated on the basis of geographic origin, as American, Swedish, Turkish, Czech or German. In Germany only a few cases of tularemia have been observed. In view of the infectiousness, the same regulations which govern bubonic plague research have been made applicable to tularemia research in German laboratories. To prevent entrance of tularemia from abroad, the importation into or transit through the reich of both living and dead hares and rabbits was prohibited if the animals came from Czechoslovakia, Austria, Hungary, Yugoslavia, Rumania, Bulgaria, Albania, Greece or Turkey. But after geographic distribution of the contagion became better known the bar was modified. It now applies only to Czechoslovakia, Turkey and Austria, as tularemia was rife in these countries during 1936-1937.

AUSTRALIA

(From Our Regular Correspondent)

March 15, 1938

Medical Research Council

The third session of the National Health and Medical Research Council was held in Sydney last November.

MEDICAL RESEARCH IN AUSTRALIA

The medical research endowment act, passed by the commonwealth government in July 1937, implements the recommendations of the Council for an annual endowment of medical research and, as a first contribution, the sum of £30,000 has been placed on the estimates for 1937. The Medical Research Council has granted assistance to university departments and such institutions as the Walter and Eliza Hall, the Kanematsu and Kolling institutes, and also to some ten young research workers who propose to open up new fields of work, and has made possible the initiation of concerted schemes of research on an organized and extensive scale, into the subjects of puerperal morbidity, streptococci, poliomyelitis, rheumatism and tuberculosis. In addition, a whole field of dental research will be explored and constructive work established. The council considered that it would be necessary to have the assistance of special committees, expert and representative in constitution, with reference to various aspects of the research scheme that has now been initiated. Four such committees were appointed with special reference to tropical physiology and hygiene, dental research, obstetric research and tuberculosis.

POLIOMYELITIS

Close attention was given to the present situation resulting from the epidemic of poliomyelitis in Victoria, and the public apprehension which has been caused not only in Victoria but in other states. The council reviewed epidemiologic aspects of the disease and the administrative control, and made certain recommendations concerning research. The council recommended the expenditure up to £4,000 for investigation into certain streptococci which have been found consistently in the throats of patients with poliomyelitis during this epidemic and also for certain serologic investigations which will require expensive monkey experiments.

Treatment of Lepers in Australia

Criticism of the treatment of lepers in Australia was voiced recently by Dr E. H. Molesworth, lecturer on skin diseases at Sydney University, a member of the International Leprosy Association and author of many publications on leprosy and other diseases. He declares that in Australia the attitude toward leprosy is medieval. The locking up of white lepers to make virtual prisoners of them is futile and has no justification. He

advocates the abolition of segregation and the granting to the leper a freedom of movement among his fellows. Lepers should be treated as individuals with the right to live in their own homes and the right to have hospital treatment like any other sick persons. He says that so long as the affected person has his own room and keeps away from children (who have greater susceptibility to the disease) there is not the slightest risk of infection. The public, while exposing itself to infection with tuberculosis and other dangerous diseases, still adopts a primitive attitude toward leprosy, with which the danger of infection is slight. In European cities, lepers are not segregated but are allowed complete freedom. There are a number of free lepers receiving treatment in London, and more than 150 living in Paris. In the whole of Australia the number of white lepers is about sixty. Dr Molesworth said that the greatest danger of segregation was that if a person discovered that he had contracted leprosy he immediately did his best to conceal the fact, because if he reported to the authorities he would be taken immediately to a lazaretto, there to live as a prisoner, forgotten by the world. The result was that most of the cases reported were far advanced. In such advanced cases treatment cannot be expected to give very beneficial results.

University Criticized

Prof. F. Wood Jones, who is retiring from the chair of anatomy at the Melbourne University to take an appointment in England, delivered some trenchant criticism of university affairs in a valedictory lecture at the Melbourne Town Hall. Professor Wood Jones said that the real university is one that prepares for intellectual life all those who are sufficiently intelligent to comprehend its meaning. Ostensibly Melbourne University was founded to be the "nursery of great men, of those on whom, whatever be our form of government, our true permanent welfare depends." But since the establishment of the Melbourne University sectarian influences have been at work for the foundation of residential colleges. In permitting sectarian religion to be recognized at all within the university Melbourne has handicapped itself in its attempt to cater for the intellectual life of the community. Certainly it would have been difficult to raise financial assistance from nonsectarian sources, but, once admitted, sectarian influences are extremely difficult to eradicate and are one of the most serious defects in the intellectual life of Australia. Professor Wood Jones said that the possibilities of free and stimulating discussion between teacher and student were practically nonexistent in most of the faculties of Melbourne University. Australia should aim at securing men of character and ability to fill university posts, and when they were secured there should be a much greater freedom of intercourse between staff and students than could prevail under the present conditions of understaffing. A university should be regarded as providing a mental clinic for young people rather than as a machine which enabled them in a mechanical way, to earn a living.

Marriages

- MORTIMER D. BURGER to Miss Lillian Katherine Solomon, both of Mount Vernon, N. Y. January 16.
- GLENN DE VREE CARLSON to Miss Lorraine Frances Manske, both of Dallas, Texas. Dec. 6, 1937.
- WILLIAM BENJAMIN DAVIS, College Park, Ga., to Miss Sara Astin of Palmetto in February.
- HENRY Y. HARPER to Miss Sara Eliza Vandiver, both of Anderson, S. C. February 19.
- MAX K. HIRSCHFELDER, Chicago, to Miss Edith Hirsch of Winnetka, Ill. in February.
- JOSEPH A. MACI, Canton, Ohio, to Miss Una Sanders of North Canton, February 14.
- FRANKLIN M. KRICHBAUM to Miss Jane Smith, both of Akron, Ohio. March 6.

Deaths

Charles O Day * Boston, Harvard University Medical School, Boston, 1907, member of the New England Otolological and Laryngological Society, fellow of the American College of Surgeons, consulting surgeon to the Boston Eye and Ear Infirmary, the Boston Lying-in Hospital and the Florence Crittenton Home and Hospital, Boston, and the Brooks Hospital, Brookline, aged 58, died February 23, in the Baker Memorial Massachusetts General Hospital of pneumonia

Daniel A MacLachlan, Detroit, University of Michigan Homeopathic Medical School, Ann Arbor, 1879, fellow of the American College of Surgeons, professor of ophthalmology and otology at his alma mater, 1889-1895, dean and professor of ophthalmology and otology, Detroit Homeopathic College, 1889-1912, formerly member of the state board of medical examiners, on the staff of the Grace Hospital, aged 85, died, February 8, at Dunedin, Fla., of cardiovascular disease

Charles Arthur Wallbillich, New Orleans, Tulane University of Louisiana Medical Department, New Orleans, 1905, fellow of the American College of Surgeons, member of the Louisiana State Medical Society, at one time professor of clinical gynecology and obstetrics at the Tulane University Graduate School of Medicine, on the staff of the Charity Hospital, aged 57, died, February 10, of cerebral hemorrhage

James L B Gilmore, Holly Hill, S C, Medical College of the State of South Carolina, Charleston, 1881, member of the South Carolina Medical Association, past president of the Orangeburg County Medical Society, also a pharmacist, for many years postmaster of Holly Hill and trustee of the schools, aged 79, died, February 19, in the Tri-County Hospital, Orangeburg, of carcinoma of the prostate

John Vincent Littig * Major, U S Army, retired, Boston, Rush Medical College, Chicago, 1901, fellow of the American College of Surgeons, served during the World War, was appointed a major in the medical corps in 1920 and retired in 1932 for disability in line of duty, aged 61, died, February 2, in the Walter Reed General Hospital, Washington, D C

Lee Chamberlain Stillings, Bellows Falls, Vt., University of Vermont College of Medicine, Burlington, 1893, member of the Vermont State Medical Society, past president of the Windham County Medical Society, served during the World War, on the staff of the Rockingham General Hospital, aged 68, died, February 21, in Knoxville, Tenn., of pneumonia

Guy Forsyth Cleghorn, Mineola, N Y Albany (N Y) Medical College, 1904, member of the Medical Society of the State of New York, past president of the Nassau County Medical Society, on the staff of the Nassau Hospital, health officer, for many years county jail physician, aged 59, died, February 6, of cerebral thrombosis and hypertension

Cornelius John Carr, Buffalo, Niagara University Medical Department, Buffalo, 1896, member of the Medical Society of the State of New York, on the staffs of the Emergency Hospital, St Mary's Infant Asylum and Maternity Hospital and the Millard Fillmore Hospital, aged 70 died, February 12, of cerebral hemorrhage and arteriosclerosis

Frederick Sefton, Auburn, N Y, Yale College Medical Department, New Haven, 1884, member of the Medical Society of the State of New York and the American Psychiatric Association, bank president, formerly member of the board of education, on the staff of the Auburn City Hospital, aged 78, died, February 3, of arteriosclerosis

Howard Coleman Scott, Sweetwater Texas, University of Tennessee Medical Department, Nashville, 1900, member of the Tennessee State Medical Association past president of the Nolan-Fisher Counties Medical Society, aged 76 on the staff of the Sweetwater Hospital, where he died, February 11 of complications following burns

Richard A Poole, Indianapolis, Medical College of Indiana Indianapolis, 1905, member of the Indiana State Medical Association, at one time county coroner formerly superintendent of the City Hospital, aged 58, died, February 24 in St Vincent's Hospital of uremia as the result of an injury received in a fall five years previously

Joseph E Moser * Bloomington, Ind State College of Physicians and Surgeons, Indianapolis 1907, served during the World War, past president of the Monroe County Medical Society, at one time secretary of the county board of health on the staff of the Bloomington Hospital aged 58 died February 1, of heart disease

John Nicholas Ryan * Passaic, N J, Long Island College Hospital, Brooklyn, 1899, served during the World War as one time member of the board of education, city health officer, superintendent of the Passaic Municipal Hospital, aged 61 on the staff of St Mary's Hospital, where he died, February 1 of duodenal ulcer

Lawrence Swante Bernhard Lundwall, Gardner, Mass., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905, member of the Massachusetts Medical Society, formerly city physician, on the staff of the Henry Heywood Memorial Hospital, aged 61, died, February 11

Edward Treen Hare, Holyoke, Mass., University of Vermont College of Medicine, Burlington, 1929, member of the Massachusetts Medical Society, aged 35, on the staffs of the Shriners' Hospital for Crippled Children and the Wesson Memorial Hospital, Springfield, where he died, February 17, of spinal meningitis

Robert Dayton Luster * Granite City, Ill., St Louis University School of Medicine, 1903, past president of the Madison County Medical Society, served during the World War formerly member of the state board of health, aged 58, on the staff of St Elizabeth's Hospital, where he died, February 11 of ileitis

James Martin Miller * Major, M C, U S Army, Ancon Canal Zone, University of Pennsylvania Department of Medicine, Philadelphia, 1917, served during the World War, entered the medical corps of the U S Army in 1920 and was promoted to major in 1930, aged 47, died February 21, in the Gorgas Hospital

Elmer E Morrison * Great Bend, Kan., Barnes Medical College, St Louis, 1896, past president of the Barton County Medical Society, fellow of the American College of Surgeons, for many years member of the school board, aged 69, on the staff of St Rose Hospital, where he died, January 18

Zachary Amerigo Mollica * Belmont, Mass Medical College of the State of South Carolina, Charleston 1912, superintendent of the Harley Private Hospital, served during the World War, aged 49, died, February 1, of coronary thrombosis while at sea aboard the S S *New York*

George Stillman Loveren * Santa Barbara Calif., Jefferson Medical College of Philadelphia, 1907, fellow of the American College of Surgeons, on the staffs of the Santa Barbara General, Santa Barbara Cottage and St Francis hospitals, aged 53, died, February 3, of cerebral thrombosis

Irving Lee Walker, Cold Water, N Y, Columbia University College of Physicians and Surgeons, New York 1901, at various times on the staffs of the Binghamton (N Y) Hospital, Central Islip (N Y) Hospital and the Rochester (N Y) State Hospital, aged 65, died, February 18

Howard Arthur Bassett, Lowville, N Y, College of Physicians and Surgeons, Boston, 1905, member of the Medical Society of the State of New York, served during the World War, aged 62 died February 12 of coronary thrombosis, diabetes mellitus and cirrhosis of the liver

Edgar J March * Canton, Ohio, College of Physicians and Surgeons Baltimore 1884, member of the House of Delegates of the American Medical Association, 1911-1912, for many years president of the staff of the Aultman Hospital, aged 81 died February 20, of coronary thrombosis

Thomas Sheridan McCabe, Newark, N J, College of Physicians and Surgeons Baltimore, 1902, member of the Medical Society of New Jersey, served during the World War on the staff of St James Hospital, aged 61, died, February 2 of coronary thrombosis and nephritis

Charles McKinley, Strong Kan., University of Kansas School of Medicine, Kansas City, 1906, mayor, member of the school board at one time physician at the state penitentiary Lansing, aged 64, died, February 15, in St Mary's Hospital Emporia of carcinoma of the liver

John Norton Thorpe * Chicago, College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1904 served during the World War, aged 61 on the staff of the Evangelical Hospital where he died February 8 of carcinoma of the stomach

Levi Brimmer Salmans, Guaymas Mexico, Kentucky School of Medicine Louisville 1891, a retired medical missionary, formerly superintendent of the Good Samaritan Hospital aged 82 died January 29 in the Huntington Hospital Pasadena, Calif

William Edwin Bradley * Estherville Iowa, Rush Medical College Chicago 1892 past president and secretary

the Emmet County Medical Society, on the staff of the Coleman Hospital, aged 72, died, February 12, of cirrhosis of the liver and lymphoma

Hiram Roscoe Gilliam, Houston, Texas, University of Louisville (Ky.) Medical Department, 1909 member of the State Medical Association of Texas, aged 65, died, February 11, in the Memorial Hospital, of pyloric stenosis, duodenal ulcer and pneumonia

Robert Woods Colville, Mount Vernon, Ohio, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1882, past president of the Knox County Medical Society, formerly member of the local board of education, aged 86 died, February 5

Dwight Addison Mathes Ⓢ Jefferson, Iowa, University of Kansas School of Medicine, Kansas City, 1931, formerly associate in general surgery at the State University of Iowa College of Medicine, aged 35, died suddenly, February 10, of heart disease

William Sparks McElrath, Cedar Bluff, Ala., Memphis (Tenn.) Hospital Medical College, 1900, member of the Medical Association of the State of Alabama served during the World War, aged 62, died, February 2, of diabetes mellitus

Henry A. Hart, Memphis, Tenn., National University of Arts and Sciences Medical Department, St. Louis 1912 member of the Tennessee State Medical Association aged 54, died, February 21, in St. Joseph's Hospital, of hypernephroma

Isaías Joseph Altwer, New York Magyar Királyi Pazmany Petrus Tudományegyetem Orvosi Faltulasa, Budapest, Hungary, 1891, aged 73, died, February 11 in Monticello, N. Y., when he severed his jugular vein with a scalpel

Joseph Peter Hanlon, Hudson, Mass. Baltimore Medical College, 1903, member of the Massachusetts Medical Society for many years school physician, aged 64 died February 4, in Lakeville, of tuberculosis of the larynx and lungs

William Porter Hughes, Russellville Ala., Kentucky School of Medicine, Louisville, 1896, member of the Medical Association of the State of Alabama aged 69, died, February 14, at Florence, of heart disease and arteriosclerosis

Conrad Favaro, West New York, N. J., Georgetown University School of Medicine, Washington D. C., 1927 aged 35, died, February 14, in the Hospital for Joint Diseases, New York, of streptococcal meningitis and multiple sclerosis

Hagop B. Asadoorian, Pasadena, Calif., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1888, at one time coroner in Carbon County, Utah, aged 76, died February 8, of coronary thrombosis

TREATMENT OF FRACTURED PATELLA WITH EXTERNAL PURSE STRING

To the Editor—A simple but effective procedure has been found of service in the conservative treatment of simple or comminuted fractures of the patella. After the blood has been removed from the joint and the thigh flexed on the body with the leg in extension by some such apparatus as a Thomas splint, an external purse string is applied to the patella in the following manner. Pressure pads are applied and fastened by adhesive tape to the periphery of the patella, partially unrolled bandages well compressed will suffice. Then a length of elastic rubber tubing is carried around the pads, drawn snugly and clamped. It is well to use a small pad on each side of the patellar ligament. If a pad is placed on the ligament, the force applied will tend to tip the lower fragment forward, i. e., the fracture line will be forced away from the joint.

This method holds the upper fragment to a lower position than can be obtained by strapping, because the adhesive strapping slips over a period of time. The adhesive slips in this method but is compensated for by the constant tension of the rubber.

W. CRAIG HENDRICKS, M.D., Brookville, Pa.

ADMINISTRATION OF CALCIUM SALTS

To the Editor—In Queries and Minor Notes (THE JOURNAL, March 19) a correspondent, inquiring about the use of calcium salts in asthma, is told to use "tricalcium phosphate 4 Gm in milk three times daily, calcium lactate 2 Gm four times daily or calcium gluconate 4 Gm four times daily." The recommendation of the use of tricalcium phosphate in milk as a method of administration of calcium is so much at variance with what is known about calcium absorption that it seems desirable to call attention to the following experimental data and basic facts.

In 1927 Roe and Kahn (Absorption of Calcium from the Intestinal Tract of Human Subjects, THE JOURNAL, March 26, 1927, p. 980) observed a 91 per cent rise in the blood calcium of a normal human subject given 5 Gm of calcium lactate in water by mouth and only a 28 per cent elevation of the blood calcium in the same subject on another day when given 5 Gm of calcium lactate in milk hourly for eleven hours (a total administration of 55 Gm). Similar failures to elevate the blood calcium appreciably when calcium lactate was given with carbohydrate or protein meals as compared with the response given when administered in water under fasting conditions were noted. These results demonstrated clearly that milk is an undesirable vehicle for the therapeutic administration of calcium and that the best results are obtainable when calcium salts are given not mixed with foods.

The results of Roe and Kahn were explained as being due to the influence of the digestive fluids on the absorption of calcium. The absorbability of calcium is dependent on its solubility which in turn is influenced by the pH of the intestinal contents. Calcium phosphate is highly insoluble in a neutral or alkaline medium. Calcium carbonate and the calcium salts of the higher fatty acids likewise have a low solubility under similar conditions. The introduction of foods into the intestinal tract brings forth a secretion of bile and pancreatic and intestinal secretions which are alkaline fluids. As the acid chyme entering the duodenum is neutralized by these fluids and the pH of the intestinal contents shifts toward the alkaline range, the solubility of calcium phosphate or calcium bicarbonate or calcium salts of fatty acids is diminished and finally when the reaction reaches a neutral or alkaline pH these salts are quite insoluble and the absorption of calcium

if present as any of these compounds, becomes very slight. It is clear then that the most favorable absorption of calcium from the intestinal tract is obtained when the drug is administered free from the influence of foods. For these reasons the therapeutic procedure of administering calcium compounds in water or fruit juices from one-half to one hour before meals has been widely adopted.

The advice to your correspondent also raises the question of whether calcium phosphate should be used at all in the administration of calcium orally. The chemical and physiologic facts mentioned are opposed to such usage. Even though the acid calcium phosphate is administered, the objection still remains that the phosphate becomes a chemical precipitant of calcium as soon as the pH of the intestinal tract reaches a neutral or alkaline range. Further space need not be consumed here to show that the experimental data in the literature on this subject indicate conclusively that calcium is best absorbed when administered as one of the salts which does not include a calcium precipitating ion when the pH of the intestinal tract is increased.

Apparently the use of calcium phosphate has come about as an attempt to increase the nutritive supply of inorganic phosphate as well as to supply calcium. Even granting the desirability of making available to the organism an increased amount of phosphorus, a better result would be obtained by administering calcium and phosphorus as constituents of other compounds than calcium phosphate and not simultaneously. But the desirability of the administration of phosphate for nutritive purposes, when there is ingested the usual diet which contains phosphoproteins and phospholipids and which normally brings about the excretion in the urine of from 1 to 3 Gm of phosphate, as P_2O_5 per twenty-four hours, is as yet unproved.

Professor of Biochemistry, George Washington
University School of Medicine

BENZEDRINE SULFATE

To the Editor—No one who has the advance of medicine and the safety of the public at heart can fail to agree with the main tenets of the editorial which appeared in THE JOURNAL March 19 entitled "Benzedrine Sulfate—A Warning." No powerful drug should be sold over the counter, nor should it for any purpose whatsoever be self-administered. This reproach does not apply, of course, merely to benzedrine sulfate but to the wide and indiscriminate use of bromides, barbiturates and even the apparently innocuous vitamins.

However, there are certain definite exceptions to take to the editorial in reference to the specific article with which it concerns itself, namely, the article by us on obesity. In the first place, these patients were selected from an internist's (Dr. Lesses') office practice and, on the whole, would not be distinguishable from the bulk of obese patients. True, they were mainly anhedonic but the point of the paper is that in large measure obesity represents an impaired appetite and impaired activity of anhedonic nature and the value of the drug used lay in the fact that it helped counteract these symptoms and thus enabled the patient to carry out more adequately the dietary treatment prescribed. Your statement, therefore, that "even if benzedrine could be safely and effectively used to reduce weight there is no evidence that it will have any permanent effect on weight" is entirely beside the point. No drug operates ad infinitum. No drug in itself produces the fortitude of character and the discipline or personality by which individuals keep their weight down to normal after it has once been brought to this level. The diabetic patient has to keep on using insulin, which is no argument against insulin and there is no guarantee that the proper use of digitalis will keep the heart muscle normal after the digitalis is discontinued.

As to addiction, the drugs to which human beings become addicted are the narcotics. There is no evidence in the entire literature of medicine that stimulants become habit forming. Alcohol, morphine, cocaine—to select a few—are narcotics, and it is a necessary part of the habituation process that larger and larger doses are required to produce the effect. One of us (Myerson) has had clinical experience with benzedrine sulfate for more than two years in a very large number of cases and has not seen a single case of addiction in the sense that a person, otherwise well, now feels it necessary to take the drug habitually and in ascending doses to produce a desired effect. The bad effects of an overdose of benzedrine sulfate immediately bring about a cessation of its use. Automatically the patient drops it. Even caffeine, which is a powerful stimulant, is never used as a drug, it is used as a beverage, and until benzedrine sulfate is introduced as a beverage no one need fear in any consequential manner drug addiction.

The abuse of a drug is no argument against its use. Normal fatigue demands rest, and this is its only cure. Abnormal intake of food demands normal intake if obesity is finally to be cured. All any drug can do is to help the individual under proper supervision to reach those habits of mind and body which finally bring about and preserve health.

Boston

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

INDUSTRIAL POISONS, WAR GAS AND LEUKEMIA

To the Editor—I am much interested in the pathogenesis of leukemia. Have cases been reported following industrial poisoning? Is there any known relationship to war gas poisoning or have cases been reported following such exposure?

M.D. New York

ANSWER—The evidence that leukemia may develop following various types of industrial poisoning is only fragmentary and certainly questionable. The evidence is indirect and includes a few reported instances of leukemia following exposure to toxic agents, particularly benzene and radioactive materials, including radium and x-rays.

Concerning the development of leukemia after the exposure to benzene in industry, Falconer (*Am J M Sc* 186:353 [Sept.] 1933) reported an instance of lymphatic leukemia in a white man four years after an attack of acute benzene poisoning by inhalation. He suggested that the leukemia may have developed as an overcompensatory measure for previous destruction of leukopoietic tissues.

Delore and Borgomano (*J de med de Lyon* 9:227 [April 20] 1928) reported an instance of leukemia developing in a man who had been exposed to benzene for five years, using it as an extracting agent in the manufacture of aminopyrine.

Alice Hamilton (*Industrial Toxicology*, New York, Harper & Brothers, 1934, p. 163) refers to an observation of Martland, who noted a blood picture characteristic of myelogenous leukemia in a patient with benzene poisoning. Also she has seen two such cases herself.

There is certain experimental evidence to indicate the possible association of benzene poisoning with leukemia. If benzene is injected into laboratory animals, the usual result is a suppression of hematopoiesis. Thus, aplastic anemia is the usual result not only in laboratory animals but in persons suffering from benzene poisoning. However, Bungeler (*Klin Wchenschr* 11:1982, 1932) administered small doses of indole to mice and was able to produce a wide variety of hematopoietic pictures, which included apparently leukemic states in a few of the animals. Also Lignac (*Klin Wchenschr* 12:109 [Jan 21] 1933) injected mice with benzene and reported leukemic blood pictures in some of the animals. Bernard (*Sang* 8:28, 1934) injected tar into rats and observed leukemic blood pictures in a small percentage of them.

It appears possible that any agent such as benzene that is known to be capable of producing suppression of marrow activity could conceivably, when used in smaller doses, produce various degrees of marrow hyperplasia resulting in the development of the leukemic states. The Parsonses (*J Ind Hyg & Toxicol* 20:124, 1938) have reported two instances of severe granulopenia after exposure by inhalation to ethylglycol monomethyl ether, which is a component of methyl 'cellosolve' used in stiffening shirt collars. Furthermore, Greenburg and his associates (*J Indust Hyg & Toxicol* 20:134, 1938) found a shift toward granulocytic immaturity in all of nineteen employees engaged in this work and disturbed erythropoiesis in nine.

Development of leukemia after exposure to radioactive substances also seems possible. Carman and Miller (*Radiology* 3:408 [Nov.] 1924) reported an instance of lymphatic leukemia in a radiologist, and von Jagic and his associates (*Berl Kl Wchenschr* 48:1220, 1911) cited three cases of lymphatic leukemia after excessive exposure to radium. Also Weil and Lacassagne (*Bull Acad de med Paris* 93:237 [March 3] 1913) observed an instance of typical myelogenous leukemia in a person who had been working with radium and thorium. Weil (*Presse med* 33:1297 [Sept 30] 1923) observed two instances of myelogenous leukemia in persons who had been working with radioactive substances. Concerning this question Martland (*THE JOURNAL*, Feb 16, 1929, p. 552) said: "The opinions of different authorities all agree that contact with radioactive substances and x-rays frequently produces a leukopenia, more rarely a leukemia. All workers with x-rays and radioactive substances are potential candidates at any time for the development of a serious and fatal anemia or leukemia." On this basis it would appear indicated in all instances of leukemia to investigate possible contact with such agents.

There seems to be no relation between leukemia and war gas poisoning. Gilchrist and Matz (*Special Bull Chem. Warfare Service U S Army, Washington, D C, Government Printing Office, 1933*) made a careful study of representative groups of the 70,752 United States soldiers who were gassed during the World War and among the various complications leukemia was not noted. This study included persons who had been gassed with chlorine, mustard gas, phosgene and arsine.

Matz writes: "As far as I know from a study of a large group of veterans who were actually gassed during the World War I am unable to find any cases which gave residual evidence of chronic myeloid or lymphatic leukemia or acute leukemia immediately following the gassing. In addition, I have gone over a number of publications on the effect of gassing administered both experimentally and during actual warfare and find no reference or evidence of a causal relationship. Accordingly, I am of the opinion that there is no relationship between warfare gassing and leukemia."

OPERATIONS IN EPILEPSY

To the Editor—A patient with traumatic epilepsy from an automobile accident has asked about the treatment of epilepsy by removing the top of the skull to relax irritated brain attachments. Any information that you can give me will be appreciated.

M.D. Virginia

ANSWER—Decompression or trepanation for convulsions was the earliest proved adventure of man into the field of major surgery. The surgical approach to the brain for the treatment of convulsions is therefore not a recent or new method. In all cases of epilepsy in which trauma is actually or thought to be a factor a careful neurologic, psychiatric and encephalographic examination is indicated for the sole purpose of determining whether or not the convulsive seizures are due to either an idiopathic convulsive state or a definite organic disturbance involving the meninges, the cortex or the subcortical brain tissue. Removing the top of the skull to relax irritated brain attachments in idiopathic epilepsy is useless, according to neurologic surgeons. If careful examinations show definite evidence of organic involvement of the meninges, cortex and subcortical brain tissue and if the auras and history of the convulsion have a definite causal relationship between the onset of the trauma and the beginning of the convulsions, surgical intervention is indicated. It has been well established that if the brain is injured and the damaged cerebral tissue is removed a scar of fibrous astrocytes connective tissue is newly formed blood vessels develop. This scar soon becomes densely adherent to the overlying meninges and like all cicatricial tissue, contracts. Otto Foerster and Wilder Penfield (*Epilepsy and the Convulsive State*, Baltimore, Williams & Wilkins Company, 1931) have described the mechanism of pull of the cicatrix and the pathologic changes occurring in the

scar tissues removed at operation Loyal Davis of Chicago states that the pathogenic relation between the formation of a scar in the brain as the result of an injury, the development of a vascular plexus, the steady pull of the contracting scar, and epileptiform seizures is definite Only the careful study of patients will answer the question of the wisdom of the surgical excision of scar tissue for the relief of post-traumatic epileptic seizures Davis's group of patients who were operated on were limited to those who had organic evidences of the severity of their original injury, those who had organic symptoms following their convulsions and those in whom encephalographic studies demonstrated a mechanical defect His results have been definitely encouraging Even though the scar can be removed surgically, however, it may be necessary to give the patient bromide or phenobarbital postoperatively

SOFTENING CITY WATER SUPPLIES

To the Editor—I have a question pertaining to water softening on a commercial scale for my particular city We have very hard water which comes from wells This is chlorinated and rates high as far as purity and taste are concerned However I am interested in the degree of softness possible Is there any valid reason why municipal water plants should not soften their drinking water? Is the process expensive? Does it affect the taste of the water in any way? How generally is water softened in cities of 30 000?

M D Ohio

ANSWER—As a general rule, in a community having an objectionably 'hard' public water supply, it can be readily demonstrated that the extra cost of soap and other compounds for water "softening" by domestic, commercial and industrial consumers would be more than sufficient to pay the cost of softening the entire water supply for the community The cost of the softening process would depend on the degree of hardness of the water originally and on the extent to which it is desired to soften

The chemicals most commonly used in softening public water supplies are lime, lime and soda ash or base exchange materials known as zeolites, which are silicates containing sodium

With proper control over the chemical treatment of the water softening process, the palatability of the water should not be affected

The softening of public water supplies as an economic measure as well as one of public convenience has developed rapidly during the last ten years, especially in the central western and southwestern sections of this country

HABITUATION TO SEDATIVES AND WITHDRAWAL

To the Editor—A member of my family a woman 39 years of age has suffered from insomnia for about two years The onset followed the sickness and death of her baby at the age of 3½ months So far as I know she has no unusual worries and is apparently in good general health She has been examined by a competent internist a professor of gynecology and a professor of neurology all of whom report nothing abnormal At the birth of her child pentobarbital sodium was used and she since has taken various members of the barbituric acid series She is able to sleep quite well under a sedative but seems unable to sleep otherwise On several occasions no sedative was taken and the next day found her completely exhausted and highly nervous Warm drinks bromides and nightly warm baths are without effect I have been advised by the men who have seen her that she should choose the lesser of two evils namely the sedative They seem to agree that it is better for her to take something and sleep rather than take nothing at all and be miserable the entire next day I cannot make myself believe that any sedative frequently repeated is without harm I believe it should be stopped but how to stop it is quite another thing Can you suggest some help?

M D New York

ANSWER—Although the barbiturates are not considered to be habit forming drugs in the strictest sense of the term, instances similar to the one described are common Dependence is placed on the drug to induce sleep and the patient is unable to go to sleep without it

After a period of use as long as the one described it is difficult, if not impossible, to withdraw the drug suddenly unless a substitute is used which is milder in action The barbiturates as a class comprise the more powerful hypnotics and sedatives The simple bromides are among the mildest of the sedatives In substituting a bromide for a barbiturate there is an abrupt change in sedative power In a case such as described the following method may be tried The barbiturate is stopped and in its place a drug which is midway in sedative action is substituted such as carbromal (U S P XI) This is diethyl-bromacetil urca and is not a barbiturate This may be given in doses up to 1 Gm if needed about a half hour before bedtime The dose is reduced gradually until perhaps 0.3 Gm is sufficient Then a solution of sodium bromide is substituted This is then gradually reduced as the patient regains his ability to sleep The bromide is then discontinued The process may

be somewhat slow and the time of withdrawal of all sedation somewhat long, but if persisted in the patient will become accustomed to sleep without sedatives

It would seem advisable in this case to attempt to find the underlying cause of the insomnia If this could be removed, permanent relief might be hastened

HERPES SIMPLEX IN TROMBONE PLAYER

To the Editor—I am asked to give advice to a nationally famous trombone artist who asks I am continually bothered with fever blisters on my lips Would you advise me to play while I have them? What should I do to prevent them?

M D Illinois

ANSWER—The present theory of the etiology of herpes simplex is based on the presence in the fluid from herpes vesicles of a virus that causes herpes on the cornea of animals when inoculated and often is absorbed, causing an encephalitis This virus is filtrable, withstands drying, and is destroyed by a temperature of 56 C and by bile It is pathogenic for rabbits, guinea-pigs, cats, dogs and mice but not for cold blooded animals or for birds It is neurotropic in animals and dermotropic in man

The filtrate of an emulsion of brain of herpes encephalitis can be inoculated on the cornea of another animal and will cause herpes there and often encephalitis It is thought, therefore, that the various diseases and physical, actinic or nervous traumas, all the influences formerly thought of real etiologic significance, are only provocative They cause a lowering of the resistance to the herpes virus, already latent in the tissues, allowing it to act and cause a vesicular eruption The nerve endings in the skin or mucous membranes seem to be the tissues acted on by the virus Most persons harbor the virus, according to this theory, but maintain enough resistance to keep it ordinarily in abeyance

Biberstein and Jessner (Untersuchungen zur Herpesfrage, *Arch f Dermat u Syph* 173 48, 1935) found that the application on scarified skin of a sterilized emulsion of the brain of rabbits or guinea pigs with herpes encephalitis caused no reaction in persons with symptomatic herpes, the ordinary form, but regularly caused a reaction in those with recurrent herpes Apparently the recurrent form of herpes is accompanied by a hypersensitiveness to the herpes virus With repeated use of the vaccine in this way they succeeded in desensitizing eleven of thirteen patients treated

Early in this century Plesch had inoculated himself with serum from a vesicle of his own eruption and thereafter was free from herpes for many years, though he had had attacks frequently before this He then treated patients in this way with many successes Others have used this method with varying results Schmidt (Vaccination for Herpes, *Arch Dermat & Syph* 32 106 [July] 1935) reported four cases in which treatment was given in this manner Two of the patients were free from herpes for two years after one inoculation The other two required a second treatment after which they had no further attacks The first vaccination caused a local reaction in all, redness, warmth and slight elevation In one patient there were a general reaction chilly sensations and nausea for a short time several hours after the inoculation Neither of the second inoculations caused a reaction of any kind

Alcoholic drinks, strong condiments and tobacco should be avoided Autoserum or autoblood injections have been of service in preventing recurrences Ultraviolet irradiation of the site of the herpes and roentgen rays in divided doses between attacks are helpful Cinchophen has been of service in preventing recurrences on the mucous membranes Phenobarbital in doses of 0.05 Gm has been successful in the experience of Laurent (Un traitement nouvelle de l'urticaire de l'herpes et du zona par le phényl éthyl malonyluree [phenobarbital] *J de med de Paris* 56 268 [March 26] 1936) Drinow (Note preliminaire sur le traitement de l'herpes et du zona par le vitamine C [acide ascorbique], *Ann de dermat et de syph* 7 817 [Sept] 1936) claims that vitamin C in a 0.1 Gm dose intravenously once a day caused the rapid clearing of the herpes eruption but he was not able to prevent further attacks except in the menstrual cases in which the recurrences could be predicted

The most popular treatment of herpes is the frequent dabbing of the vesicles with spirit of camphor Some patients prefer to apply lotio alba (sulfurated potash 1 Gm and zinc sulfate 1 Gm in 30 cc of rose water) This should not be kept long, for it deteriorates

It seems advisable for the trombonist to refrain from playing when afflicted with herpes for irritation may increase the frequency of the attacks

ACQUIRED OR CONGENITAL SYPHILIS IN PREGNANCY

To the Editor—Please summarize for me the best methods for treating the following case of syphilis. A primipara married nine years whose husband has diabetes missed two periods and the signs and symptoms are those of a pregnancy. A Wassermann test several years ago was positive. She cannot recall primary or secondary signs of syphilis. She was given neosarsphenamine and after a few treatments had a severe arsenical dermatitis. After about six weeks she was able to return for treatment and bismuth injections were used. She again had a severe dermatitis. Since then she has been unable and afraid to take injection therapy but has taken mixed therapy by mouth. Her Wassermann reaction is now two plus. A spinal Wassermann test has not been taken. Her reflexes are normal. Her general condition is good and she has no complaints. She believes she has congenital syphilis because her mother and brother have both been found to be infected. The serologic reaction of her father is negative.

M D West Virginia

ANSWER—It is rather important in this case that the question of congenital syphilis or acquired syphilis be answered. It makes a great deal of difference in the outlook for the patient and certainly for the unborn child. The fact that the mother has syphilis and the father has a negative serologic reaction is of course suggestive that the patient may have congenital syphilis. It is stated that there are no manifestations of active syphilis. On the other hand, is there any evidence of a keratitis, of Hutchinson's teeth, of mulberry molars, of eighth nerve deafness or of saber shins? Is there a history in the past of cutaneous manifestations of any type that would suggest prenatal syphilis? Certainly if the patient has congenital syphilis one need not worry particularly about the outcome as far as the unborn child is concerned. For the present it is suggested that she be put on intramuscular injections of colloidal mercury sulfide Hille, 3 cc twice a week, for probably ten weeks. If there is any question as to the patient's having congenital syphilis as against acquired syphilis, it might be well for a consultant to see the patient. In case this is acquired syphilis, attempts should be made to use arsenical therapy as well. In patients who are sensitive to neosarsphenamine it is sometimes possible to employ some other arsenical, for example, mapharsen, starting off cautiously in small doses. If the patient has acquired syphilis, and if it is in any way possible, she should receive therapy with alternating courses of arsenic and mercury until the birth of the child.

GOLDTHWAITE AND ELY SIGNS IN LOW BACK DISEASE

To the Editor—Please explain the Goldthwaite and Ely signs used in the differentiation of conditions in the lower part of the back. How are they performed? What are the pathologic conditions present to cause a positive sign and what is the clinical significance of each?

M D California

ANSWER—The test used in the differentiation of disorders in the lower part of the back which has sometimes been attributed to Goldthwaite is simply that of straight leg raising. This test has to be interpreted on the basis of leverage transmitted through the hamstrings to the pelvis. It is performed correctly by flexing the thigh with the knee extended and the foot held in a position of 90 degrees dorsiflexion in order to keep the gastrocnemius, as well as the hamstrings, taut. The leg should be raised slowly with one hand under the lower part of the patient's spine. As the hamstrings tighten, leverage is gradually applied to the side of the pelvis. If pain is brought on before the lumbar spine begins to move, a lesion which may be either an arthritis or a sprain of the ligaments involving the sacroiliac joint is probably present. If pain does not come on until after the lumbar spine begins to move, the disease or injury may be in either the sacroiliac or the lumbosacral articulations but is more likely to be lumbosacral. The straight-leg raising test should be repeated on the side opposite to that of which the patient primarily complained. In this instance, if the lesion is lumbosacral, pain should be felt when the leg is raised to approximately the same height as that which produced pain when the leg was raised on the side complained of. If the lesion is primarily sacroiliac it should be possible to raise the leg on the less involved side to a much higher level than on the side complained of without pain. Acute or chronic inflammation of lumbosacral or sacroiliac joints due to trauma, such as an acute or chronic back strain or to infection such as tuberculosis, pyogenic arthritis or degenerative changes in the articulations themselves, may be the predisposing factors.

The Ely sign has rarely been mentioned in discussions of pain in the lower part of the back. In 1933 Ely stated in an article (*Backache Lumbago, Pain in the Lower Part of the Back, Arch Surg* 27 189 [July] 1933) that hyperextension of the leg at the thigh with the patient lying face downward would produce pain if there was a lesion in the lumbar spine or at the lumbosacral joint. In a letter Oct 25 1937 sent in response to a

direct query, Dr Ely stated that this test should be performed with the patient lying prone and the knee flexed. If the test is positive the pelvis will rise from the table before complete extension of the thigh. The author of the test stated that it was not able to determine the exact significance of it but believed that it was positive when there was an irritative lesion low down in the lumbar spine. The studies of Ober, Williams and Goldthwaite would suggest that this sign might be due to a tight iliotibial band and attempt at hyperextension of the thigh would tend to rotate the pelvis downward and to sharpen the angle between the lumbar spine and the sacrum, mechanically contributing to the irritation of the lower lumbar nerve roots.

It would seem that a positive Ely sign is simply one more indication of a lumbosacral lesion.

ERUPTION OF TEETH AND OSSIFICATION OF BONE IN DETERMINING AGE

To the Editor—Which is the more authentic in determining the age of a person roentgenograms of the long bones or of the teeth? The claimed age is 4 years and 8 months. From the long bones such an age is possible but the pictures of the teeth show that this person has erupted permanent teeth which according to various charts should not be. According to the charts the boy is at least 8 years old. He has the following permanent teeth:

| | |
|------------------|---------------------------|
| Central incisors | two upper and two lower |
| Lateral incisors | both lowers |
| First bicuspid | both right and left lower |
| Second bicuspid | left lower |
| First molar | both right and left lower |

It is the opinion of those to whom the question was put that at the age of from 4 to 9 the roentgenograms of the teeth would be more certain in determining the approximate age as the time in which the teeth are erupting is rather certain. However, after all the teeth have erupted the long bones might be a better method of determining age. I should like to obtain a comparison of the two methods of determining the age of a person particularly a person between the ages of 4 to 10. As this case is coming to early trial, I would appreciate an early reply.

M D, Washington

ANSWER—The time at which teeth erupt is not an invariable or absolute one. The period of eruption varies not only with the age of the child but also with the rate of body growth in general. Taller children cut their teeth earlier than smaller children. It has also been maintained that there is a relationship between eruption of the teeth and growth and size of the palate. It has not been possible to correlate in point of time the eruption of the teeth to the ossification of the bones of the wrist. It goes without saying that there is a strong relationship between the state of nutrition and the eruption of teeth. Mineral or vitamin deficiency may retard the eruption considerably. Racial and economic differences may also influence the period of eruption. While the temporary teeth appear at intervals with some regularity, the permanent teeth appear with considerable irregularity, and the intervals between the eruptions may vary within wide limits. It is obvious from these considerations that neither the eruption of the temporary or the permanent teeth offers definite or invariable information as to the chronological age of the child.

Age Periods at Which Certain Bones Undergo Ossification

| | Girls | Boys |
|----------------------------------|-------------------|-------------------|
| Os capitatum (os magnum) | Between 3 & 6 mo | Between 4 & 10 yr |
| Os hamatum (unciform) | Between 3 & 6 mo | Between 6 & 12 yr |
| Os triquetrum (cuneiform) | Between 2 & 3 yr | With 3rd yr |
| Os lunatum (semilunar) | Between 3 & 4 yr | With 4th yr |
| Os naviculare (scaphoid) | Between 4 & 5 yr | With 5th yr |
| Os multangulum minus (trapezoid) | Between 4 & 5 yr | In 5 & 6 yr |
| Os pisiforme (pisiform) | Between 9 & 10 yr | In 12 & 13 yr |

Using the carpal bones as an index, various investigators have established the difference between the ossification periods that occur in boys and in girls. The accompanying table enumerates the age periods at which under normal conditions, these bones undergo ossification in both sexes.

In considering both of these methods of establishing chronological age, the evidence seems to indicate that neither method should be expected to give absolutely correct values. Both methods should be considered only approximate and subject to numerous variations. All things considered however the bone development would probably give a more approximately correct index than the sequence of tooth development.

It must be assumed also that such abnormal conditions as congenital syphilis, hypothyroidism, glandular disturbances, and avitaminoses such as rickets do not enter into the picture. In these diseases after the time of eruption of the teeth and the progress of bone development to a considerable extent.

EXTREME HYPERGLYCEMIA

To the Editor—A patient brought into the hospital in diabetic coma had a blood sugar on admission of 1500 mg per hundred cubic centimeters. This was checked several times. Within twelve hours the blood sugar was down to 750 mg and this was the last reading before he died. Will you kindly inform me whether similar blood sugars have been reported before?

M D Minnesota

ANSWER—Lawrence reported a blood sugar reading of 2060 mg per hundred cubic centimeters in a patient who had received 40 units of insulin two hours previously. This is the highest value recorded in the literature. Blood sugars of 1,710 and of 1,700 mg occurred in cases reported by Argy and by Pitfield.

Dillon and Dyer record the highest blood sugar value in a patient who survived, the patient entered the hospital in diabetic coma with a blood sugar of 1,850. These authors report fifteen other cases with admission blood sugars of 1,000 mg or more, five patients recovered.

Joslin, reviewing the subject of extreme hyperglycemia reports blood sugar values of 1,000 mg or over in thirteen of 338 consecutive cases of diabetic coma. Of the thirteen patients, eight recovered. The highest blood sugar value in his series was 1,620 mg, occurring in a patient who survived. Joslin concludes that although blood sugar values of from 300 to 600 are the rule in diabetic coma, a high blood sugar does not necessarily imply a poor prognosis.

COMPLICATIONS OF PARATYPHOID INFECTION

To the Editor—Please send to me any information you have regarding the lung and intestinal involvements and febrile reactions in paratyphoid A infection. I have recently had a patient who seems to have persistent lung and intestinal symptoms and low grade fever. Please advise also as to the use of vaccines, serums and the like in treating this phase of the disease.

RALPH L MOORE MD Woodbury N J

ANSWER—It is difficult to answer these questions specifically without knowledge of how the lung and intestinal involvements manifest themselves. Lung complications are thought to be more common with paratyphoid A infections than with either typhoid or paratyphoid B. Bronchitis is almost as much a part of the disease as is the fever. The bronchitis usually subsides during the second week but may persist throughout the entire course. Bronchopneumonia and even lobar pneumonia are not infrequently encountered. These are not as a rule due to the paratyphoid bacillus but are caused by secondary invaders. Lung abscess and gangrene and pulmonary infarction occur infrequently and as the result of embolism. Pleurisy, either serofibrinous or suppurative, occurs somewhat more frequently. Pulmonary tuberculosis occasionally follows paratyphoid. It is doubtful that the disease imitates a tuberculous process, but it probably allows a latent tuberculous focus in the lung to become active.

The disease extensively involves the intestinal tract and this in itself may produce diarrhea, distention or abdominal pain. The organisms may be found in the bile in almost every case and it would seem that this would predispose the patient to cholecystitis, cholangitis and hepatitis, and yet these complications are rather rare. Invasion of the mesenteric lymph glands occasionally produces long continued abdominal pain and discomfort. Abscess of the spleen has been reported but this also is rare.

The question does not state how long the infection has lasted in this patient. Fever often persists a long time. It is thought that such patients have difficulty in developing a complete immunity to the disease. Relapse after a free period of ten days or two weeks sometimes occurs and the course of the relapse may be quite atypical. Any of the complications mentioned could produce a long continued low grade fever. This is particularly true of infected mesenteric glands, which might also produce abdominal distress and discomfort. Another possible obscure cause for fever is venous thrombosis. A favorite place for such thrombosis is the abdominal or pelvic veins or the veins of the leg. It is in such cases that the embolic phenomena are likely to occur.

There is no evidence to show that the use of vaccines or serums is of any value in the treatment of the acute phase of

the disease. Foreign protein shocks are sometimes used to call forth additional immune bodies but the use of foreign protein shocks may be disastrous in the presence of some of the possible complications in this case. Their use should not be considered unless their safety can be assured.

ELEMENTS AND HUMAN BODY

To the Editor—How many positively known elements are there now? How many positively known elements are there that enter into the composition of the human body? Please give me the names of the last ten elements discovered and the approximate dates.

GEORGE C CROSTON MD Sapulpa Okla

ANSWER—At present eighty-eight different elements are recognized, if isotopes are not included. The last one, which is not named, was discovered in 1931. The other ten of the most recently found elements are helium (1895), neon (1898), krypton (1898), xenon (1898), radium (1898), lutecium (1907), hafnium (1923), radon (1925), rhenium (1925) and thulium (1926). The elements found in protoplasm which are known to be of biologic value are hydrogen, carbon, nitrogen, sulfur, oxygen, phosphorus, iron, copper, zinc, manganese, sodium, potassium, calcium, magnesium, chlorine, fluorine and iodine. Those of doubtful value in protoplasm are bromine, arsenic, aluminum, nickel, silicon, strontium, cobalt, selenium, vanadium and lead. Traces of many other elements may possibly be found in tissues, but their presence probably is accidental.

EFFECT ON BODY OF HIGH TENSION
ELECTRIC CURRENT

To the Editor—1 If a person standing on the ground took hold of a wire conveying 66 000 volts would it be possible for him to live five or six hours? 2 Under these conditions what would be the probable condition of the body? 3 Would it be possible for a person to let go before death of a wire carrying 66 000 volts? Any references to the literature will be greatly appreciated.

M W HAWS MD Fulton Ky

ANSWER—1 It is difficult for a person to "take hold" of a wire carrying a current of 66 000 volts with bare hands. High tension currents usually arc before actual contact is made and muscular contraction will frequently cause the body to fall away from contact, though arcing once established may extend for long distances. Because of poor contact and its brief duration, efforts at resuscitation are more successful in high tension shocks than in any other type. It is possible but improbable that the victim might live five or six hours after the shock without artificial respiration. Recovery has been reported after continuous artificial respiration for eight hours.

2 The body should show electrical burns at least in regions of proximal contact. Heat burns from ignited clothing are frequently present.

3 See answer to question 1.

Specific data are available in MacLachlan, Wilks. Electric Shock. Interpretation of Field Notes, *J Indust Hyg* 12 291 (Oct) 1930, 16 52 (Jan) 1934.

An extensive bibliography accompanies the paper on Effect of Electric Shock on the Heart, by Ferris L P, King, B G, Spence, P W, and Williams, H B. *Electrical Engineering* 55 498, 1936.

PAROXYSMAL RAPID BREATHING

To the Editor—A man has spells of rapid respiration during which he breathes from fifty to sixty times a minutes for from a few minutes to as long as half an hour. He can tell when the spell is coming on by a feeling of faintness but he never faints. This condition is much worse in summer especially if he is in a stuffy room or working in the heat. The lungs and heart are normal. I would appreciate any information regarding other cases of a similar nature if any.

FREDERICK J VOLLMER MD Howard S D

ANSWER—This patient has a hysterical or neurasthenic tachypnea. Such cases are well recognized. Ronald V Christie (Some Types of Respiration in the Neuroses, *Quart J Med* 4 427 [Oct] 1935) found that an important fraction of all patients classified as suffering from neuroses had respiratory complaints. These were easily recorded on the tracing of the metabolism apparatus. There were several types of respiration that which this patient has occasional sighing constant moderately rapid deep respirations and irregular breathing. In extreme cases the overventilation is continued until alkalosis and tetany occur. The induction of the tetany in such cases was found to be a requirement of the hysteria.

Associated neurotic symptoms are usually present, such as suffocation globus hystericus palpitation, coldness, tremor and sweating so that if the cardiac symptoms are pronounced the case is usually classified as neurocirculatory asthenia.

ACRIFLAVINE IN GONORRHEA

To the Editor—While sojourning in England I chanced to visit the general hospital at Birmingham, England. They used intravenous acriflavine in more than 5 000 cases of acute gonorrhea with excellent results. I have been looking over *THE JOURNAL* but cannot find anything on this method. Will you inform me if there is any danger in its use 2 per cent from 2 to 4 cc. once every second day?

G. GLENN WHITE, M.D., San Diego, Calif.

ANSWER—If references in American literature concerning the use of intravenous acriflavine therapy in acute gonorrhea reflects its popularity in this country, it is definitely not in vogue. Acriflavine is one of the many dyestuffs discovered by Ehrlich to have bactericidal value. In the treatment of gonorrhea it has been given orally, subcutaneously and intravenously, and it has been used as an irrigation and as an instillation.

Edward Hughes and C. A. Birch (*Lancet* 2:633 [Sept 16] 1933) reported using acriflavine in more than 100 cases of acute gonorrhea. They used the drug subcutaneously and found the injections to be painful. Intravenously 10 cc. of 1 per cent solution was injected three times a week. They state that its use may lessen the number of complications but in fifty cases found three cases of epididymitis and three cases of acute arthritis. The average duration of gonorrhea under this treatment was 116 days. As complications due to the drug, several thromboses of the vein occurred, two cases of jaundice and one generalized rash. Therefore the drug may cause liver damage and apparently does not control gonorrhea as well as more recent methods of therapy.

ARTIFICIAL PENIS

To the Editor—About eight months ago a man had an amputation of the penis the amputation removing about one half of the shaft. Recovery has been uneventful and complete. He has been happily married for seven years to a highly sexed woman. There have been no pregnancies but no contraceptives have been used at any time. As a result of his condition and her sexual make up they are at the present terribly unhappy and unless something can be done will undoubtedly separate. Are there any concerns that might make an artificial penis?

M.D., Michigan

ANSWER—Some dealers in surgical instruments are reported able to make an artificial penis with a belt around the abdomen. It is not unusual for attempts at intercourse to enlarge the organ and an extreme case, even worse than that described, is reported by Max Huhner in "The Diagnosis and Treatment of Sexual Disorders in the Male and Female, Including Sterility and Impotence" (Philadelphia, F. A. Davis Company, 1937, p. 113). It is also possible by artificial means to enlarge and develop the organ to a remarkable degree.

MALARIAL BLOOD FROM PATIENT WITH DEMENTIA PARALYTICA FOR DEMENTIA PRAECOX

To the Editor—Would it be inadvisable to take blood from a patient with dementia paralytica who has undergone the malarial treatment just before the treatment has been stopped and inject it into a patient who has dementia praecox? Would there be any possibility of the spirochete being still viable after the hyperpyrexia treatment and would there be any probability of transmitting the organism to the new patient?

M.D., North Dakota

ANSWER—There would be only slight danger that the blood from the patient with dementia paralytica would contain *Spirochaeta pallida*. This is not because the fever of the malaria kills spirochetes but because the blood of patients who have dementia paralytica contains few if any spirochetes.

The injection of malarial blood from a patient with dementia paralytica into a nonsyphilitic patient is, of course, open to criticism in the case in question because malarial therapy has been of no particular value in the treatment of patients with dementia praecox.

COITUS AFTER DELIVERY AND CURETTAGE

To the Editor—What is the proper interval after which coitus may be permitted following a normal delivery? After cesarean section? After curettage? What risk is involved in premature resumption of coitus in such cases?

M.D., California

ANSWER—Coitus should not be indulged in before the patient is examined about six weeks after a baby is born. The reasons for this are that, before six or eight weeks following childbirth, involution of the genital organs is usually not complete and a repair of lacerations or an episiotomy may not be completely healed before this time. Furthermore, there is some likelihood of starting a flow of blood from the uterus before this time and also presumably there may be some risk of intra-uterine infection from coitus. However, many couples indulge in coitus before a new-born baby is 6 weeks old and aside from

the discomfort experienced by the woman, serious consequences are seldom observed. The six weeks abstinence period applies to women who have had cesarean sections as well.

Following a curettage performed for diagnostic purposes in the absence of a pregnancy, there is no harm in indulging in coitus two weeks after the operation. However, if the curettage is performed for a condition of pregnancy such as therapeutic or incomplete abortion, it is best to have the patient avoid intercourse for at least four weeks to permit complete involution of the genitalia and to avoid the possibility of an intra-uterine infection.

NECK INJURY AND COCCYGEAL PAIN—NERI TEST

To the Editor—Is there an anatomic reason or sympathetic nerve connection that would cause pain in the area of the coccyx when there is some injury to the cervical spine? A man struck the back of his head just above the axis. A short time afterward pain developed in the area of the coccyx although he never injured the lower part of his spine. This happened two years ago. The head neck and coccygeal pains virtually disappeared but lately the coccygeal pain has returned without any special cervical symptoms. A woman never had an injury of any kind. She has been noticing for the last month that on moving her neck or when sitting in a chair with the head forward she has pain in the area of the coccyx. Roentgenograms in both cases are negative.

M.D., New Jersey

ANSWER—There is no anatomic connection between the cervical region and the coccyx except through the cerebrospinal fluid. In the presence of arthritis with radiculitis, a spinal cord tumor or equina tumor, such acts as coughing, sneezing or straining at stool will increase the intraspinal pressure and aggravate the discomfort.

There is a test known by the name of Neri, which is called the nodding test, which is positive when simple nodding of the head increases intraspinal pressure and causes radicular pain.

PRURITUS IN PREGNANCY

To the Editor—Can you give me information on the etiology and treatment of a generalized pruritus manifesting itself in the latter months of pregnancy? I have attended three sisters who have this condition in the latter months of pregnancy. The mother had similar trouble. There is no glycosuria. The itching which is intense at times is first noted in the feet and legs then becoming generalized. It is immediately relieved after delivery. It would seem that the mothers were allergic to the products of conception. It is not an urticaria and is not relieved by epinephrine.

M.D., North Dakota

ANSWER—The cause of generalized pruritus in pregnancy is not definitely known but it is presumably related to the toxemias. H. Vignes (*Gynecologic* 36:88 [Feb.] 1937) reported a series of forty-one cases of pruritus vulvae during pregnancy and fourteen cases of extragenital pruritus associated with gestation. He could not detect a common factor in these cases. Since the cause is not known, the treatment must be empirical. Patients may be relieved of their itching by local applications of equal parts of magnesium magna and olive oil. Oatmeal baths are also helpful in many cases. Three cups of cooked oatmeal in two quarts of water should be placed in a cloth bag securely tied at the top and placed in the bath water. These baths may be taken as often as desired.

STRYCHNINE AND ALCOHOL

To the Editor—Is it true that the giving of strychnine with whisky is poison or vice versa? As one of the treatments for alcoholism is 0.3 to 0.5 grain (0.002 Gm.) of strychnine taken for ten days a good cure?

J. E. FRENCH, M.D., Holy Grove, Ark.

ANSWER—The conclusions of Dr. Norris's studies are absolutely not applicable to the ordinary or therapeutic use of strychnine, as well as of whisky, although they do apply to almost lethal quantities of these substances. Strychnine (0.002 Gm.) may be used safely in the treatment of alcoholism.

NASAL SEPTUM OPERATION AND PACKING

To the Editor—In the answer to a question in *Queries and Minor Notes* in the March 26, 1938 issue entitled "Nasal Septum Operation Without Packing" I get the impression that you discourage the use of nasal tubing in each nostril to allow nasal breathing because the inspired air is not moistened by the nasal mucosa. But 90 per cent of a leaf is less than none. The real cause of discomfort from packing the nose is from mouth breathing and the lack of moisture for so short a period is not noticed by the patient. If one insists on moist inspired air this can be managed by directing steam from an inhalator toward the nose. If one blocks the nose so that he could not breathe I think he will be satisfied to forego the lack of moisture for twenty-four hours and resume nasal breathing.

EMANUEL ROTH, M.D., Flushing, N.Y.

Book Notices

Reports on Chronic Rheumatic Diseases Being the Third Annual Report of the British Committee on Chronic Rheumatic Diseases Appointed by the Royal College of Physicians Number Three Edited by C W Buckley MD FRCP Cloth Price 10s 6d \$3 50 Pp 131 London H K Lewis & Co Ltd New York Macmillan Company 1937

This volume of reports, the third offered by the British committee reviews recent investigations on joint disease and offers a critical survey of the present status of various forms of therapy Throughout the reports there is in general a clear differentiation between that which is known and that which is unproved

In a sane article on vaccines and rheumatoid arthritis, Okell discusses the rationale underlying vaccine treatment He points out that it is not reasonable to treat with vaccine a disease the cause of which is unknown

Reviewing the use of sympathectomy in arthritis, Learmonth finds relief of pain to be the most constant result, but the cause of the relief is not known An article on roentgen therapy in chronic arthritis contributed by Kahlmeter, gives a review of the results in the experience of other workers and of his own results in 4,000 cases The most suitable types of cases and the limitations of the method are discussed The evidence for the possible association of vitamin deficiencies as precipitating factors in rheumatic diseases is surveyed by Race in a valuable article on vitamins and rheumatic diseases Two cases of neutrophil leukopenia with enlargement of the liver and spleen in rheumatoid arthritis are reported by Collins Recent studies on the changes produced in joints by hypercalcemia on the serum calcium phosphorus and phosphatase in bone diseases on the deposition of colloidal matter in the reticulo-endothelial system about joints and on the incidence, characteristics and course of Still's disease are reviewed briefly by Moncrieff In a review of the recent results of chrysotherapy in arthritis, Tegner indicates the basis for his conclusion that this form of treatment is of benefit in rheumatoid arthritis in spite of the dangers of complications The summary of recent work on osteo-arthritis by Clarke presents briefly the factors that are responsible for the degenerative changes and the difficulties of treatment In an article on diet in arthritis Buckley reviews the results of the use of recently advocated diets An

excellent review of recent American investigations by Hench covers the observations in the various types of joint disease. In discussing the value of sodium salicylate in the treatment of gout, Jennings indicates the appearances necessary for a diagnosis of gout and presents the comparative results of sodium salicylate and cinchophen treatment. The possible dangers resulting from the administration of such commonly used drugs as acetophenetidin, aminopyrine and cinchophen are presented clearly by Archer and Discombe. Brief abstracts of articles from the Italian, French and German literature are given by Bach and Pether.

The book is of value to all interested in present lines of investigation in joint disease and in the evaluation of various forms of treatment.

Tuberkulose. Ein Fortbildungskursus der Berliner Akademie für ärztliche Fortbildung im Tuberkulosekrankenhaus der Stadt Berlin "Waldhaus Charlottenburg". Herausgegeben von H. Ulrich, ärztlicher Direktor des Waldhauses Charlottenburg und O. Koch, Prosektor am Waldhaus Charlottenburg. Unter Mitarbeit von G. Ballin et al. Paper. Price 6.60 marks. Pp. 147 with 42 illustrations. Berlin: Julius Springer 1937.

In this booklet the fundamentals of the pathology, epidemiology, diagnosis and treatment of the tuberculous lesions located in the various organ systems of the body are given in a short and precise manner. The theory of Ranke and its subsequent evolutions are discussed and chapters dealing with the influence of hereditary and constitutional factors, with the effect of associated diseases, age and pregnancy, are included. Pathologic, microscopic and serologic examinations and the results of other laboratory procedures such as blood counts, determination of the sedimentation rate, and tuberculin tests are evaluated. A chapter is devoted to the technic and usefulness of the functional test of the lung, with evaluation of the spirometric method. Tuberculosis in childhood, the indications and technic of collapse therapy and the indications for phrenic exeresis, thoracoplasty and pneumolysis are discussed. Separate chapters are devoted to tuberculosis of the larynx, bones, intestine and genito-urinary tract. The social problems, the problems of public health and effective tuberculosis prophylaxis are discussed. The printing of the book is well done, with excellent reproductions and sketches. While the book does not contain new points of view or original work, it will be a valuable addition to the library of the student, of the general practitioner and of the specialist as a source of quick orientation as to diagnosis and therapy.

Organization, Strategy and Tactics of the Army Medical Services in War. By T. B. Nicholls, M.B., Ch.B., Lieut. Colonel Royal Army Medical Corps. With a foreword by Lieut. General Sir James A. Hartigan, K.C.B., C.M.G., D.S.O., Director General Army Medical Services. Cloth. Price \$4. Pp. 372. Baltimore: William Wood & Company 1937.

The medical service in modern warfare has enormous duties to perform. It must not only treat the wounded and the sick but must provide for them food, clothing, shelter, warmth, pay, discipline and transportation. This book seems to deal with every problem that a medical officer in the field may encounter. It is based largely on experience in the World War. Some of the terms used pertain especially to the British army and its medical service. In modern warfare it is essential to estimate before a battle the size of the medical problem that will develop. Before the World War it was calculated that 6 per cent of the force engaged in any one battle would become casualties. This estimate was far exceeded in France, where, in some battles, 20 per cent of the forces engaged became casualties in the first forty-eight hours and 40 per cent by the end of the first week. Assuming the strength of a division to be 20,000, the medical service has to prepare to deal with from 4,000 to 8,000 casualties in each division. In one battle in the World War the advance information was to prepare to care for 20,000 casualties, there were actually 60,000, or the equivalent of three entire divisions. Estimating that seventy-eight trains are required to move one division, 234 trains would have been required to move this number of casualties, and these passengers are patients, most of whom have to be carried to the trains. There is another problem of the greatest importance involved in a task so huge. It has been said that the side which can produce a last 100,000 men will win a war. This last 100,000 may be in the hospitals ready, or nearly ready to be returned to duty. If the medical service is inefficient in returning men to

the front as soon as possible, that might have much to do with winning or losing a war. Cron, an Austrian general, previous to the World War devised a formula with which to estimate the casualties in modern warfare. The Cron formula, the author says, as applied to many of the battles in France, gave average results not far from the mark. Cron estimated that only three fifths of a total force would be engaged in actual fighting and that 10 per cent of them would become casualties, so his formula is that the total number of casualties will be 10 per cent of three fifths of the total force, or 6 per cent. There is nothing certain in war, and no one formula could possibly give an accurate forecast of the casualties. The author discusses other methods of estimating the number of sick for whom the medical service must provide. He tabulates the approximate casualties in many engagements in the World War and figures the percentage in relation to the total force. He discusses the various medical units and their organization from the front line back to the base. He gives supply tables for the various units, showing the personnel required and the equipment. He discusses the considerations that enter into the location of the main dressing station, taking up such details as how many splints to provide for each unit, and how many stretchers and operating lamps. There never seems to be a sufficient number of stretchers in any large engagement, there should be a reserve of at least 300 for every division. There are chapters on ambulance trains, general hospitals, hospital ships, convalescent depots, depots of medical stores, lines of communication, organization of the base, strategy and tactics, and examination and promotion in the medical service.

Uric Acid in Blood and Urine. By Knud Brøchner Mortensen. Paper. Price 9 Danish kroner. Pp. 269 with 58 illustrations. Copenhagen: Levin & Munksgaard 1937.

This book contains a comprehensive and critical review of methods for the determination of uric acid in blood serum and in urine. The author reports new methods of his own as well as suggestions for careful control of conditions in methods previously reported. A large series of analyses gives comparative results of the commonly used methods and of his methods. Studies of serum and the uric acid content of the urine for normal persons were performed; the results of which are reported in detail. Uric acid clearance studies, total daily excretion of uric acid and the effect of diet and of diuresis are all studied in detail. The mechanism of uric acid excretion is considered. All persons used for study were free from any disturbance of uric acid metabolism. The bibliography of nearly 400 references indicates the comprehensive nature of this book, which should be a useful work of reference for persons interested in metabolism of uric acid or in methods for its determination.

The Cerebrospinal Fluid. By H. Houston Merritt, M.D., Assistant Professor of Neurology, Harvard Medical School, Boston, and Frank Fremont Smith, M.D., with a foreword by James B. Ayer, M.D. Cloth. Price \$5. Pp. 333 with 17 illustrations. Philadelphia & London: W. B. Saunders Company 1937.

The literature on cerebrospinal fluid has become so voluminous in the last few years that it is hard for the average physician to get a clear picture of what is practical and what is theoretical. A book on the subject particularly by men who have spent many years in studying the fluid is therefore of great value. Both authors have had an enormous experience in the study of cerebrospinal fluid and have kept an accurate record of their cases so that they can tell by actual numbers how many specimens of fluids in a certain disease showed changes and how many did not. The book covers almost every neurologic condition known. The general practitioner as well as the neurologist can therefore use the book with profit. There are a few criticisms, however, that might be leveled at the book, the most important of which is that the authors have been too set in their opinions. As a result they omit mention of some pertinent information. For instance, in their admirable discussion of cerebrospinal fluid pressure they state that they use a certain water manometer but fail to mention the fact that there are other manometers on the market which are considered efficacious. While they devote some space to the comparison of the measurement of pressure by mercury and water manometer and justify the use of the latter, they do not mention that mercury and other manometers may be

used. They likewise fail to evaluate a good many tests that have been popular. For instance, no mention is made of the tryptophan test for tuberculous meningitis. Possibly the authors do not consider it reliable, but in a book on the subject one would expect some discussion as to its value or at least some mention of it. With regard to the Kahn test the authors do state their opinion that "most serologists are agreed that the various precipitation tests do not give as satisfactory results in the cerebrospinal fluid as in serum" (p. 61), but one might doubt the accuracy of this statement. In discussing the hydrogen ion concentration of the cerebrospinal fluid the authors submit a 1925 reference on the p_H of normal cerebrospinal fluid, whereas this was pointed out as early as 1917. This, however, may be ascribed to an oversight. Throughout the book a good deal of space is devoted to topics on which the authors have done special work. While this is forgivable it results in a disproportionate emphasis on those subjects as compared to other subjects in which they did comparatively less work. The book fulfils the one purpose of the authors (as expressed in the foreword) to present facts, but it does not fulfil the other purpose to explain why some changes take place. In their desire to be practical the authors have at times neglected the theoretical or rather philosophic outlook of cerebrospinal fluid. As a whole, the book is practical and authoritative.

Textbook of Experimental Surgery By J. Markowitz M.D. Ph.D. M.S. in Exp. Surg. Research Associate, Department of Physiology, University of Toronto. Cloth. Price \$7. Pp. 527 with 330 illustrations. Baltimore: William Wood & Company, 1937.

Written in brief yet discursive and pleasant style, this short volume comprises a rapid introduction to the field of experimental surgery. The author maintains that the practical lessons in technique and physiology learned first hand on the laboratory animal is the surgeon's greatest asset. He asserts that many clinicians have much to learn of practical physiology of the "Bernardian" type and that less emphasis might be laid on highly theoretical chemical effects such as surround the problem of insulin. He lays much stress on actual surgical technique, detailing much space, for example, to the choice and method of suturing. Included also is a chapter on the antiseptic movement, in which the author advises constant vigilance against the fanatics and the ill informed. The chief virtue of this book lies in the fact that the author works from the assumption that his readers know little about practical surgery. Therefore he submits physiologic explanations for even the most simple steps in any procedure. This, coupled with the patient detail in illustration, lends much value to the short textbook, which should be appreciated especially by the postgraduate student in surgery.

Arteriovenous Aneurysm. Abnormal Communications Between the Arterial and Venous Circulations By Emile Holman A.B. B.A. M.D. Professor of Surgery, Stanford University Medical School, San Francisco, California. Cloth. Price \$6. Pp. 244 with 79 illustrations. New York: Macmillan Company, 1937.

This monograph, dealing with arteriovenous aneurysms of various types, is a splendid example of the value of experimental work in the clarification of clinical problems. Details of laboratory procedures for the establishment of arteriovenous fistula in animals are given and the physiologic reasons for development of the various symptoms are explained in detail. By various experiments the author proves that the sudden drop in blood pressure following establishment of an arteriovenous aneurysm is due to an increase in blood volume and that recovery of the pressure to normal after closure of the fistula is enhanced by dilution of the blood by incoming plasma. The cardiac output is found to be increased as much as twofold in arteriovenous fistula. The cardiac hypertrophy which results after a large fistula has been present for some time is discussed in detail. The rapid subsidence of this hypertrophy following repair (as depicted by x-ray and clinical means) is readily explainable on the basis that the cardiac load imposed by the fistula has been eliminated. Methods of repair of the accessible fistulas after the principle laid down originally by Matas are discussed in detail. Sufficient data are presented to prove rather conclusively the advocacy of ligating the vein simultaneously with the artery whenever ligation is the procedure of choice. The various procedures for the treatment of intracranial fistulas

are discussed in detail. This portion of the monograph is particularly valuable because the author has clearly demonstrated that the fatal results of immediate ligation of the internal carotid artery can be eliminated by trial ligation and digital compression. Important points in the treatment of congenital fistulas, such as the elimination of all the fistulous channels, are properly emphasized. Two separate chapters are devoted to a consideration of patent ductus arteriosus and congenital intracardiac fistulas. The last seventy-five pages consist of protocols of patients and animal experiments dealing with the various types of fistulas. An adequate bibliography is an attractive feature of the monograph. It is doubtful whether the reader will find the various features of arteriovenous fistulas discussed elsewhere in the medical literature with as much clarity and consideration of the physiologic principles involved. The book will therefore be of great value to the neurologic surgeon as well as to the general surgeon even though such fistulas are relatively uncommon. The publishers have chosen a good grade of paper and type, which are conducive to easy reading.

Medical Uses of Radium. Summary of Reports from Research Centres for 1936. Medical Research Council Special Report Series No. 226. Paper. Price 1s. Pp. 41 with 6 illustrations. London: His Majesty's Stationery Office, 1937.

This report continues the accounts of fourteen similar earlier reports on the use of radium under the supervision of the Medical Research Council. It discusses results of purely experimental work as well as of the treatment of cancer in a number of hospitals under the direction of local committees. There are sections on cancer of the breast, the uterus, the mouth, nasopharynx, larynx and esophagus and the rectum, on sarcoma, on telurium therapy and on nonmalignant conditions. The report will interest particularly specialists in the treatment of cancer.

Phenomenon of Local Tissue Reactivity and Its Immunological Pathological and Clinical Significance By Gregory Schwartzman M.D. Bacteriologist, Mount Sinai Hospital, New York. Foreword by Jules Bordet M.D. Cloth. Price \$7.50. Pp. 461 with 68 illustrations. New York: Paul B. Hoeber, Inc., 1937.

Schwartzman has rendered an important service to medical science in bringing together and correlating in monograph form the extensive studies on his phenomenon of local skin reactivity (Schwartzman phenomenon) accumulated during the past decade. The first ten of the thirteen chapters of the volume deal with laboratory investigative aspects of the phenomenon, while in the last three chapters the author attempts to correlate his phenomenon with related phenomena in pathology and immunity, discussing particularly the significance of the phenomenon and its clinical application. The latter is in the experimental stage, and definite procedures of diagnostic and curative value, based on the Schwartzman phenomenon, are yet to be established. The phenomenon is of dramatic interest. If a small amount of bacterial filtrate is injected into the skin of a rabbit, a slight inflammatory reaction will appear in the area of injection in about twenty-four hours. If at about that time the animal is injected intravenously with the same bacterial filtrate or with some other bacterial filtrate or indeed with reagents of non-bacterial origin the mild inflammatory area in the skin undergoes hemorrhagic necrosis in a few hours. The preparatory skin injection must be made with a substance of bacterial origin while the 'provocative intravenous injection does not have to be made with a substance of bacterial origin. Schwartzman argues that he is dealing in this phenomenon with a new category of toxins and antitoxins and that his phenomenon is entirely distinct from the phenomenon of anaphylaxis and tissue hypersensitiveness. In connection with the Arthus reaction he states on page 352. All the evidence considered together sharply differentiates the phenomenon of local tissue reactivity described in this monograph from the 'Arthus phenomenon'. Yet forty pages later (p. 391) he states that the necrotic and hemorrhagic reactions of the Arthus phenomenon in man belong at least in part to the domain of the phenomenon of local tissue reactivity. Even though one may not agree with Schwartzman's interpretation of his phenomenon, the fact remains that the monograph is a provocative contribution to the medical sciences.

A Manual of Obstetrics By Thomas Watts Eden MD CM FRCP Consulting Obstetric Physician to Charing Cross Hospital and Eardley Holland MD BS FRCP Obstetric and Gynecological Surgeon The London Hospital Eighth edition Cloth Price 24s Pp 765 with 410 illustrations London J & A Churchill Ltd 1937

The appearance of the eighth edition of this standard textbook of obstetrics is proof of its popularity. Many chapters have been completely rewritten, others have been changed, and all of the material has been brought abreast of the times. Many new illustrations help to clarify the text and make the book more instructive to students and practitioners. The logical arrangement of the subject matter into eight parts is conducive to greater usefulness as a teaching textbook. All the subjects of interest in this special field are covered completely but rather briefly, thereby making it possible to confine the material within the limited number of small pages. The treatments suggested are for the most part conservative and represent accepted opinion. A few key references are listed at the end of each chapter, which with few exceptions pertain largely to the English literature. A unique innovation consists of brief summaries after most of the references. There is always room for differences of opinion with regard to certain ideas of practice. Thus, one may take specific exception to the discussion on manual dilation of the cervix. This method, like accouchement force, should no longer be considered good practice. The cervix cannot be regarded as an elastic ring which can be stretched like a rubber band. Too many grave sequelae have followed this apparently simple procedure. In the treatment of eclampsia, saline infusions are usually considered contraindicated and dangerous. Present knowledge favors the use of hypertonic solutions of dextrose. Poultices to the loins have fallen into complete therapeutic discard. The discussion on the treatment of placenta praevia is excellent and deserves commendation. The same may be said for the rational approach to the treatment of puerperal infection.

Macleod's Physiology in Modern Medicine Edited by Philip Bard Professor of Physiology Johns Hopkins University School of Medicine Baltimore et al Eighth edition Cloth Price \$8.50 Pp 1051 with 355 illustrations St Louis C V Mosby Company 1938

It has become increasingly difficult for any one man to write a comprehensive advanced textbook of physiology. In recognition of this fact, Professor Bard has enlisted the collaboration of eight colleagues in the preparation of this edition of a well established textbook. This destroys to some extent the individuality of any book but the student is unquestionably the gainer in that each section has been prepared with more care. In the preface the editor justifies the omission of the section on "The Physicochemical Basis of Physiological Processes" on the assumption that the student will have become familiar with this material in other courses—an assumption of questionable validity. Experience with large numbers of students shows that most of them need ready at hand some reference to fundamental laws and processes. While the text throughout is written in clear, lucid style, students are inclined to object that one must read too much material in order to garner a few facts. Objection is made also to the extensive use of small type, which, the editor explains, covers four kinds of material—"descriptions of methods, data judged to be of secondary interest to the student but necessary for a full understanding of the subject under discussion, treatment of matters that are at present largely controversial, and finally considerations which are chiefly of clinical interest." The illustrations are well selected and well integrated with the text. However, as in the previous edition, reproductions of photographs are often inexcusably poor. This is the most serious defect in the book. Of the textual material perhaps the section on metabolism and nutrition is the least attractive. Particularly the chapters on vitamins, on mineral metabolism and on nutrition are, in view of the importance these subjects have come to assume more recently, unjustifiably conventional and sketchy. The section on the endocrines is greatly improved over that appearing in the previous edition, but even here there is something of a conventionalized approach which one scarcely expects in a newly written work. The section on respiration seems to represent perhaps the best presentation of subject matter. Especially to

be commended is the chapter on internal respiration, as it carries material that has not been so adequately discussed in any other work. The discussion of auditory and labyrinthine mechanisms seems unduly limited. Aside from the intars mentioned, the proportionate allotment of space to the various sections seems well balanced. Thorough acquaintance with the text as a whole will give the student a well balanced conception of the important fundamentals of physiology.

Creative Camera Art By Dr Max Thorek FRPS FRSA KLB President Photographic Society of America Cloth Price \$3.50 Pp 156 with illustrations Canton Ohio Fomo Publishing Company 1937

A relatively simple way of making an acceptable photograph from a snapshot is first to have an enlargement made. On this the shadows may be strengthened and dark areas added by means of a pencil. A contact print made from the enlargement will have the black and white in reverse, so that pencil marks will appear light when the final print is made. Thus it is possible during the process to add both light and shade where they will do the most good. Dr Thorek describes the technique of picture making and discusses the creative side up to the point at which the individual worker must think for himself. Numerous illustrations show the effects that can be introduced at different stages of the paper negative process, and there are magnificent reproductions of portrait studies, genre and landscapes.

Diagnostiques urgents Abdomen Par H Mondor professeur agrégé à la Faculté de Paris Fascicules 1 et 2 Third edition Cloth Price 210 francs per set Pp 524, 527 1119 with 248 illustrations Paris Masson & Cie 1937

The popularity of this treatise on diagnosis of acute conditions within the abdomen is best proved by the fact that only four years elapsed between the second and the present edition. Contrary to the prevailing custom the book has been only slightly enlarged—seventy-three pages more than the second edition, what is still more surprising, the number of illustrations has been cut, apparently without detracting from the value of the book. A cursory perusal of the voluminous two parts failed to reveal any signs of a considerable revision. The colloquial style and numerous case histories are responsible for the large size of the work, certainly an undesirable feature of a book of this type, which should serve as a guide in emergency cases. It seems that not enough attention has been paid to the laboratory studies, frequently invaluable in the differential diagnosis of acute abdominal conditions. Such minor criticisms do not detract from the value of this exhaustive and comprehensive work, which should be of interest to every man practicing abdominal surgery.

Eight International Congress of Military Medicine and Pharmacy and Meetings of the Permanent Committee Brussels Belgium June 27 July 3 1935 Report of Captain William Seaman Bainbridge M C F Member of the Permanent Committee for the Delegation of the United States of America Department of State Publication 1069 Conference Series Cloth Price \$1 Pp 114 with 3 illustrations Washington D C Supt of Doc Government Printing Office, 1937

The late King Albert of Belgium and Queen Elizabeth created the first International Congress of Military Medicine and Pharmacy in 1921. Since then there have been meetings every second year in various large cities in Europe, at which representatives of numerous countries have met to study the problems of military medicine and surgery and to concern themselves with the alleviation of suffering in possible future wars. Capt. William Bainbridge, U S Naval Reserve, retired, who has attended each of the eight conferences as an official delegate of the United States government or unofficially at his own expense, has reported each one of these congresses. In the present report there is a foreword by Charles R Reynolds Surgeon-General, U S Army. The congress is organized in two main sections (1) the International Office of Medical Military Documentation and (2) the Medico Legal Commission which is forming an association for the international protection of humanity, with headquarters at Monaco. A list is given of the official delegates to the eighth congress from the various countries represented. There were ten official delegates from the United States. The remainder of the small volume comprises the report of the various meetings and abstracts.

the addresses Among the subjects discussed were the determination of fitness for the different specialties in armies, navies and air forces, post-traumatic conditions of the abdomen, the standardization of methods of analysis of foodstuffs for military use, buccodental services at the front, principles of organization and functioning of medical services in mountain warfare, and the functions of the administrative medical services of the armies, navies and air forces A comparatively brief account of this congress was published in *THE JOURNAL*, Oct 16, 1937, page 1292, in the Belgium letter

Synopsis of Obstetrics and Gynecology By Aleck W Bourne M.A. M.B. B.Ch. Consulting Obstetric Surgeon Queen Charlotte's Hospital London Seventh edition Cloth Price \$4 Pp 452 with 175 illustrations Baltimore William Wood & Company 1937

Bourne's seventh revision draws much of the material from standard textbooks Because of his familiarity with the essential needs of the student and along with his vast clinical experience, he has been able to incorporate this material into a clear, concise, handy volume that is presented in an easily readable manner This book is also intended for setting forth the significant points in reviewing for examinations in obstetrics and gynecology The chapters covering the anatomy and physiology of pregnancy are concise, though not at the expense of clarity The toxemias of pregnancy are discussed clearly and with modern conceptions Eclampsia is treated along definitely conservative lines The chapters on postpartum hemorrhage and puerperal infection are commendatory The book should contain more illustrative diagrams The application of forceps is described only with the patient in the left lateral position For the benefit of the American readers of this book, it might have been well to give a description of forceps application with the patient in the dorsal position The estrogenic and gonadotropic factors and their relation to menstruation, puberty, the menopause and menstrual disturbances are gone into pointedly with many practical suggestions The book is well correlated and can be wholeheartedly recommended for both the student and the practitioner The author has well succeeded in his effort

The Subnormal Mind By Cyril Burt M.A. D.Sc. Professor of Psychology University of London University of London Heath Clark Lectures 1933 delivered at the London School of Hygiene and Tropical Medicine Second edition Cloth Price \$5 Pp 372 New York & London Oxford University Press 1937

Light lectures cover, in addition to a brief account of normal psychology, Burt's interpretations of the mentally deficient, the dull or backward child, the delinquent and the neurotic school child The neuroses are dealt with, in general, in two more lectures The book is a summary of abnormal psychology as visualized by a psychologist of wide training and a leader in his field The psychiatrist, although differing with some of the views expressed, will find much of value in this comprehensive but somewhat discursive book A second edition has been called for in two years It differs from the first in minor corrections and the addition of free association test material in the appendix

A Primer for Diabetic Patients An Outline of Treatment for Diabetes with Diet Insulin and Protamine Zinc Insulin Including Directions and Charts for the Use of Physicians in Planning Diet Prescriptions By Russell M Wilder M.D. Ph.D. F.A.C.P. Professor and Chief of the Department of Medicine of the Mayo Foundation University of Minnesota Sixth edition Cloth Price \$1.75 Pp 191 with 4 illustrations Philadelphia & London W. B. Saunders Company 1937

The present edition of this manual for patients was issued primarily because of its need with regard to treatment with protamine zinc insulin It gives the patient and the physician a good general outline as to how to proceed in changing from old to new insulin In this respect it is a valuable help and guide The field is well covered and the manual as a whole gives a good and reasonable type of information to the patient At the end of each chapter there is a series of questions covering the chapter and in order to answer these the patient has to have the grasp of the contents This is a good type of instruction, not the ordinary parrot type of learning This being the sixth edition the author has had ample opportunity to make changes in the text so that the present volume is the crystallization of the subject as applied in practice

The Structure and Composition of Foods By Andrew L Winton Ph.D. and Kate Barber Winton Ph.D. Volume III Milk (Including Human) Butter Cheese Ice Cream Eggs Meat Meat Extracts Gelatin Animal Fats Poultry Fish Shellfish Cloth Price \$8 Pp 524 with 11 illustrations New York John Wiley & Sons Inc London Chapman & Hall Limited 1937

In this volume, which is devoted exclusively to foods of animal origin, the Wintons have continued their excellent summaries of the microscopic structure and the chemical composition of foods The present volume takes up milk and its products, eggs, meat, poultry, fish and shell fish In addition to a discussion of the chemical composition and properties of each food and each component, there are brief but thorough discussions of the influence of various methods of production and manufacture on the composition of foods Copious references to the original literature and a suitable index enhance the usefulness of the book This volume will take its place with the others in the series as an indispensable reference work for those who deal with the technical aspects of foods

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Act Dermatitis Following Abrasion an Accidental Injury—In the course of his employment in a woolen mill the workman repaired machinery and from time to time received bruises and abrasions on his hands He became incapacitated by reason of a dermatitis caused in the opinion of a physician, by oil, grease, dirt and bacteria coming in contact with such an abrasion on one of his hands The industrial accident commission of Maine awarded him compensation under the workmen's compensation act and his employer appealed to the Supreme Judicial Court of Maine

The employer's defense to the claim for compensation seemed to have been based on the theory that because the workman was unable to tell with exactness just when the particular abrasion was suffered and because such slight injuries were received almost daily and were dismissed by the workman when received as trifling, it was therefore a mere incident of his employment and not an "accident" within the meaning of the Maine workmen's compensation act The Supreme Judicial Court, however, believed that there was sufficient evidence to warrant the industrial accident commission in finding that the dermatitis was caused by the entry of bacteria through an abrasion on his hand That the abrasion itself was of such small consequence that the workman did not remember the exact time when it was received was unimportant, in the opinion of the court In arriving at its conclusion the court cited *Brutons Limited, v. Turvey*, A. D. 1905 230, an English case in which compensation was awarded for the death of an employee from anthrax, the germ of which entered his system through an abrasion in the corner of his eye The court also cited *Brodin's Case*, 124 Me 162, 126 A 829, in which a workman who contracted typhoid fever from drinking contaminated water furnished by his employer was awarded compensation The court in the present case could see no distinction between the entry of typhoid bacteria through the mouth as in *Brodin's case*, of the bacillus of anthrax as in the English case, and the case under consideration Accordingly the award of compensation in favor of the workman was affirmed—*Beaumont's Case (Me)*, 193 A 923

Malpractice Proof of Causal Relation Between Injury and Alleged Malpractice Necessary—The plaintiff injured in an automobile accident on the evening of March 30, 1935, was taken to a hospital in a semiconscious and partially paralyzed condition The defendant as attending physician made it was alleged only a casual examination of the plaintiff stating that he was merely shaken up Thirty six hours later the defendant permitted the plaintiff to be removed from the hospital at which time the relationship of physician and patient seems to have ended Thereafter on April 12, the plaintiff was taken to another hospital where there was discovered a dis-

location of the fifth cervical vertebra that had resulted in a compression fracture of the sixth cervical vertebra and a fracture of the pedicle lamina arches. The then attending physician undertook by traction to repair the damage but, owing to the condition and location of the injury, found it was impossible to do so. Subsequently the plaintiff brought suit against the defendant for malpractice. At the conclusion of the plaintiff's evidence the trial court entered a judgment of nonsuit and the plaintiff appealed to the Supreme Court of North Carolina.

To justify the submission of a malpractice suit to a jury, said the court, there must be evidence tending to show that the patient was injured, that the physician was negligent in the manner in which he examined and treated his patient or in his failure to render proper treatment, and that such negligent conduct was the proximate cause of the injury sustained by the patient. The burden rested on the plaintiff to prove a causal connection between his injury and the alleged negligent conduct of the defendant. All the medical expert witnesses agreed that it is risky to subject a patient to a thorough examination when he is under severe shock and that the attending physician must exercise his best judgment in determining when it is safe to make such examination. No witness testified that the plaintiff's condition was aggravated by the delay in efforts to reset the bone or that the inability to reset the bone was due to any condition arising from the delay. The evidence disclosed that the use of modern equipment and methods by trained and skilful physicians at a time when callus had not developed sufficiently to interfere with proper setting of the bone had availed nothing. The character and location of the fracture were such that proper traction could not be successfully used. Unfortunately, the plaintiff suffered an injury that could not be relieved except by the performance of a most dangerous operation. The plaintiff's unfortunate condition, in the opinion of the court, did not result from any negligent conduct of the defendant. The judgment of nonsuit was therefore affirmed.—*Gower v Davidian* (N C), 193 S E 28

Contraceptive Devices Importation of Vaginal Pessaries—Section 305(a) of the Tariff Act of 1930 provides, in part

All persons are prohibited from importing into the United States from any foreign country any article whatever for the prevention of conception or for causing unlawful abortion

The claimant, a physician of New York specializing in gynecology, imported a package containing 120 vaginal pessaries from Japan. The United States filed a libel for the forfeiture of the package, contending that its importation was prohibited by the section of the Tariff Act of 1930 quoted. The United States district court for the seventh district of New York dismissed the libel (13 F Sup 334) and the government appealed to the circuit court of appeals, second circuit.

The question before the court was whether physicians who import vaginal pessaries in order to use them for the health of their patient are excepted by implication from the literal terms of the tariff act. In the opinion of the court, the act embraces only such articles as Congress would have denounced as immoral if it had understood all the conditions under which they were to be used. The design of the act was not to prevent the importation, sale or carriage by mail of things which might intelligently be employed by conscientious and competent physicians for the purpose of saving life or promoting the well-being of their patients. While it is true, said the court, that the policy of Congress has been to forbid the use of contraceptives altogether if the only purpose of using them is to prevent conception in cases in which it would not be injurious to the welfare of the patient or her offspring, it is going far beyond such a policy to hold that abortions, which destroy incipient life, may be allowed in proper cases, and yet that no measures may be taken to prevent conception even though a likely result would be to require the termination of pregnancy by means of an operation. It seemed to the court unreasonable to suppose that the national scheme of legislation involves such inconsistencies and requires the complete suppression of articles the use of which in many cases is advocated by such a weight of authority in the medical world. The court, therefore, affirmed the decree of the district court dismissing the libel.—*United States v One Package* 86 F (2d) 737

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Scarlet Fever Immunization with Formalized Toxin—Anderson points out that preliminary Dick tests were given to more than 14,000 children, of whom 63 per cent have been found positive. Of those who began the immunizing injections 8,212 received the complete course of three injections of formalized toxin. All children to whom formalized toxin was administered had been found to be susceptible as determined by a previous Dick test usually performed the day before the first dose of antigen was given. More than 80 per cent of those injected were rendered Dick negative. Subsequent studies in communities failed to bear out these early institutional results nor were the later results in institutions as favorable. Retests show that approximately 50 per cent of those injected have been rendered Dick negative. Anything more exact than this generalization would be unwarranted as the variations between communities and within the same community have been too great ranging from 21 to more than 60 per cent. Retest of a small group of children given a second course of injections after being found Dick positive subsequent to the first series of injections showed that more than 90 per cent of these children were rendered Dick negative. The figures are too small to be significant but raise a reasonable question as to the added protection which might

accrue from further injections of formalized toxin. It is impossible to advance any significant data as to the duration of immunity induced by formalized toxin. Institutional data, however, show no significant tendency to relapse to a Dick positive reaction. Reactions following the administration of the formalized toxin have been so mild that there has been as hearty an acceptance of this immunizing procedure as has been accorded to diphtheria immunization in the same communities.

Methods of Diagnosis of Rabies in Animals—Leach states that the mouse technic of Webster and Dawson for confirming the diagnosis of rabies in animals as practiced in his laboratory is as follows. Material, when not examined fresh, is preserved in full strength glycerin. A small portion of Ammon's horn is ground up in a sterile mortar and nine parts of hormone broth added to one part of ground brain material. This is thoroughly emulsified and then centrifuged at from 2,000 to 2,500 revolutions per minute for about five minutes. With a 0.25 cc tuberculin syringe, 0.03 cc of the supernatant fluid is injected into the brain through the skull of a 4 to 6 weeks old mouse. A 27 gage needle one fourth inch long is employed, and the injection is made slightly to one side of the midline of the skull and half way between the eye and the ear. The site of inoculation is moistened with alcohol before injecting. The mice are lightly etherized before the operation. It has been the practice at the laboratory to inoculate four mice with each brain specimen. In addition to shortening the period required for animal diagnosis, the method has the advantage of reducing the cost. Comparative results from brain material of 1,032 animals diagnosed by the usual methods in several laboratories and then injected into mice confirmed the positive results obtained by the usual methods but disclosed an error of 12 per cent for the brains reported negative for Negri bodies. The vaccination or treatment of animals with rabies vaccine apparently increases the difficulty of diagnosis by the discovery of Negri bodies.

Mesenteric Lymphadenitis—Adams and Olney cite twelve cases of nontuberculous and one of tuberculous mesenteric lymphadenitis. The patients were less than 14 years of age. The average age reported by most authors is less than 20 years. Nontuberculous lymphadenitis must be differentiated from acute appendicitis, pyelonephritis, Meckel's diverticulitis and intussusception. The diagnosis is usually made at operation. The colicky nature of the pain and lack of localized symptoms in

cases which may be observed for a few hours may lead to a correct diagnosis without operation. This is especially true when there is a rapid subsidence of symptoms, a course which is often observed in this condition. Simple lymph node hyperplasia of the mesenteric nodes in the region of the ileocecal junction and, to a lesser extent, in the mesentery of the lower ileum, is the usual pathologic manifestation. Occasionally cultures of material from these nodes may yield pyogenic organisms. Exploratory celiotomy is the treatment of choice. The appendix is removed and the wound is closed without drainage. The prognosis for a permanent cure is good. Most patients remain symptom free following appendectomy.

Water Balance in Neurosurgical Patients—In addition to hemorrhage, which averages from 500 to 1,500 cc, the patient undergoing a prolonged operation for an intracranial tumor may lose up to 1,000 cc of water from his skin and lungs. White and his co-workers are concerned with what can be done to reduce this and how the disturbed fluid balance can be restored most effectively. The loss of water vaporized from the skin and lungs can be minimized by (1) the substitution for ether of local infiltration anesthesia and (2) avoidance of the use of too warm coverings in a hot operating room and in the ward. Replacement of fluid lost at operation is best carried out by the administration of a constant intravenous infusion of 5 per cent dextrose in physiologic solution of sodium chloride during all major craniotomies. The infusion should be continued in the ward until not more than 2,000 cc of fluid has run in. In this way the interstitial fluid reserve, as well as the electrolyte balance, can be maintained at slightly reduced but safe levels. Postoperatively, fluid must be replaced much more accurately in neurosurgical than in general surgical patients. A slightly deficient state of hydration is safer in patients after operations on the brain, in order to minimize cerebral edema. In the absence of vomiting or diarrhea, a 5 per cent solution of dextrose in distilled water is the preferred solution for prolonged intravenous administration. In addition to the measured output of urine, feces and vomitus, from 1 to 2.5 liters (quarts) of fluid is lost by vaporization from the skin and lungs in the course of each day. If this insensible loss is not taken into consideration, serious dehydration may develop.

Variability of Circulation Time—Freeman determined the circulation time, with other physiologic processes, at intervals of four weeks on twenty-nine normal men and thirty-two men suffering from schizophrenia. During this interval the two groups of subjects lived in the same ward, ate about the same food and went through a similar amount of activity. The mean circulation time of the schizophrenic patients was longer than in normal subjects in both series of determinations. The variability in measurements of the circulation time was greater for the schizophrenic subjects than for the normal subjects both for the individual and for the group. For this function the

homogeneity of the individual is greater than that of the group. The variability of the function is such, however, that measurement of the circulation time for a given person can be considered to be a clinical characteristic for that subject only so far as it enables one to place him as having a low or a high value. The only variable which appeared to be correlated with the circulation time is the pulse rate. This correlation was greater for the group of schizophrenic patients than for the control group.

Benzene Poisoning—Gall gives the history and histologic observations of a case of benzene poisoning. The clinical picture was that of aplastic anemia, leukopenia, thrombocytopenia and macrocytosis. The disease terminated fatally with gastrointestinal hemorrhage. There was inadequate hemopoietic regeneration exhibited by the bone marrow. Low grade reticulocytosis and the immature myeloid cells and nucleated red cells in the circulating blood were explained on the basis of the changes in the marrow. Massive metaplastic erythropoiesis was present in the spleen and to a less degree in the liver. It is believed that the metaplastic changes observed were produced as the result of atypical regeneration in a liver and spleen damaged by benzene.

Migraine in Children and Mechanism of Attack—Riley declares that migraine appearing in childhood shows a tendency to disappear at the time of puberty, and if these patients are followed over a period of years there is a definite inclination for the attacks to recur at the time of the climacterium. The headache may appear interchangeably with other manifestations of the allergic status, such as hay fever, eczema, urticaria, bronchial asthma. It may be that the essential condition is an unbalanced equilibrium of the cerebral circulation in which an abnormal condition of dilatation or constriction in certain vigorous cerebral areas exist. It is impossible to state the exact pathway over which the migrainous discomfort is transmitted to the central nervous system. According to previous

opinions, any part of the intracranial arterial or venous tree may be involved by the vasotonic process and thus give rise to the symptoms characterizing the migrainous attack. The ultimate solution of the problem of migraine will depend on the careful collection of clinical and experimental material. The real problems toward the solution of which investigation must be addressed are the questions as to what it is which results in this explosion, how the result is accomplished and why one person responds in a particular manner to a situation which in another is entirely innocuous.

Intracerebral and Extracerebral Tumors Involving Temporal Lobes—Collins gathered 108 cases of tumors of the temporal lobe verified by operation or necropsy, from the records of the Neurological Institute (seventy-four intracerebral and thirty-four extracerebral neoplasms). The duration of symptoms in patients with intracerebral neoplasms ranged from four days to ten years, while the duration in the extracerebral tumors varied from one month to eighteen years. The following symptoms showed the greatest variability: (1) Headache occurred in 17 per cent more intracerebral tumors; (2) aphasia occurred in twice the number of intracerebral tumors; (3) generalized convulsions were twice as frequent in intracerebral tumors; (4) unconscious spells were four times as frequent in extracerebral tumors; (5) jacksonian motor seizures were absent in intracerebral tumors and (6) subjective field defects were absent in extracerebral tumors. Of the more important symptoms occurring during the course of the two types of neoplasms, decreasing vision was much higher in the extracerebral tumors with the elevation occurring chiefly as a succeeding symptom, auditory symptoms were much higher in the extracerebral group, drowsiness and stupor did not occur in any instance of the extracerebral group, uncinate attacks were much higher in the intracerebral group and sensory symptoms were much higher in the extracerebral group, whereas vertigo was much higher in the intracerebral tumors. In viewing the statistics from a general standpoint and not from a comparative one between the two types of neoplasms, as far as the symptomatology is concerned neoplasms in the temporal lobes do not produce symptoms of dysfunction in a high percentage of cases. All the temporal symptoms, such as aphasia, uncinate attacks, dreamy episodes and probably auditory symptoms and subjective field defects, occurred in about 50 per cent of the cases. The most important localizing signs are contralateral hemianopic or quadrantic field defects. Neighborhood symptoms and signs play an important part in localizing and lateralizing temporal neoplasms and the most important of these is an isolated contralateral central facial weakness. Contralateral motor and sensory disturbances and in no little measure in accurate localization.

Leukemia and Neoplasms—Some pathologists believe that leukemia is a new growth of the bone marrow and the blood. In support of this view Evans gives the following clinical and laboratory observations: 1 The tumor is frequently in evidence for a long time before the development of the blood picture. This fact was evident in two of the four cases that are cited. 2 Mitotic figures (dividing blood cells) are seen in the lymph nodes, the bone marrow and rarely in the blood.

One of the cases illustrates this in the lymph nodes. In a second case there were mitotic figures in the spleen, liver, kidneys, lungs, adrenals, gastro-intestinal tract, lymph nodes, bone marrow and the circulating blood. 3 Tissues are definitely invaded by these cells. Rapid growth is demonstrated in nearly all tissues of the body. The lymph nodes in one case gave evidence of marked invasion through the capsule of leukemic cells. 4 Sensitivity of these cells to x-rays is well known and roentgen treatment and the new 'shatter' radium type of treatment is frequently effective in controlling the mass of cells in the liver, spleen and lymph nodes. 5 The tendency to skin and bone metastases is striking. The four cases of leukemia reported demonstrate one or more of the foregoing points.

Pneumoperitoneum for Pulmonary Compression

Stokes used pneumoperitoneum for pulmonary compression in fifty-five cases, most of which were unsuitable for collapse therapy. The prognoses were uniformly unfavorable. The indications for this type of compression may be subdivided as follows. It may be used as an independent procedure, preparatory to other forms of compression or collapse therapy, to supplement phrenic paralysis and to supplement unilateral pneumothorax and it may be found of some benefit in the treatment of pulmonary tuberculosis complicated by tuberculous enterocolitis. Contraindications to pneumoperitoneum for pulmonary compression are poor general health, dyspnea, exudative or acute mitral disease, large cavities, rigid diaphragm and stiff walled cavities. The duration of pneumoperitoneum in forty-one cases ranged from one and a half to twenty-four months. In the fourteen cases in which pneumoperitoneum was instituted as an independent procedure the condition is apparently arrested in one, quiescent in one, improved in four and unimproved or worse in five. Three patients are dead. Of twelve cases which it was thought, might ultimately become suitable for phrenic interruption or for surgical thoracoplasty, a thoracoplasty was performed in one and on discharge the condition was classified as arrested, the condition is unimproved or worse in six and five patients are dead. In the five cases in which either a phrenicotomy or a phrenicotomy with unsatisfactory results was performed

pneumoperitoneum was instituted with the hope that additional elevation of the diaphragm might prove beneficial, one patient has had a thoracoplasty and the condition is classed as apparently arrested, one is worse and three are dead. In the three cases in which pneumoperitoneum supplemented unilateral pneumothorax the results are also disappointing the condition is unimproved in one and the other two patients are dead. The remaining seven patients received pneumoperitoneum both for pulmonary compression and for the relief of abdominal pain caused by tuberculous enterocolitis. The results in this group are likewise poor one patient is improved, two are unimproved and four are dead. As a method of pulmonary compression, pneumoperitoneum has very limited application in the treatment of pulmonary tuberculosis. However, when other measures either fail or cannot be utilized, it may aid in the control of hemoptysis and in the reduction of toxemia.

Autohemotherapy in Pulmonary Tuberculosis—Freilich and Coe selected fifteen patients with pulmonary tuberculosis of the moderately or far advanced types for autohemotherapy. The eight women and seven men were studied for fourteen weeks and each received three treatments per week averaging fifty-two injections of from 10 to 15 cc of whole fresh blood taken from the arm under sterile conditions and injected directly into the buttocks, with the blood remaining in the syringe for an average time of fifty seconds. None of the patients received pneumothorax treatments and all were either semiambulant or confined to bed and were subjected to the standard therapeutic regimen of the hospital. After two months of treatment, six showed a gain in weight varying from 1 to 7 pounds (0.4 to 3 Kg) and averaging 4 pounds (2 Kg). Eleven patients were losing weight before the experiment began. Of these, five stopped losing, two showed a gain and four continued to lose. All the patients were subjectively improved in that they evidenced improved appetites, better mental attitudes, lessened cough and lessened sweats. Objectively the results were less pronounced. The sputums of three patients became negative after two to two and a half months of treatment. The remaining twelve evidenced no change. The physical and x-ray signs were not altered. In only two cases did the temperature come down to a normal level. Two patients died within three months after the experiment was concluded. Five of the six patients continued to gain in weight and continued to evidence subjective improvement, but the remaining eight either continued to lose in weight or maintained a stationary level. Of these eight, four pursued a downward course during the next six months and three died. No toxic effects were evidenced in any of the cases during the experiment, although five of the men had an associated arteriosclerosis and one a mild diabetes. Considering a similar group of fifteen patients treated according to the same hospital regimen, except that they received pneumothorax without any autohemotherapy, the results were not comparable in that this group made much better improvement objectively and subjectively. There was only a slight difference in favor of the group treated with autohemotherapy as compared with a similar group treated by routine hygienic-rest management without pneumothorax. This form of therapy is worthy of further trial and may be a successful adjunct to the routine treatment of pulmonary tuberculosis with and without artificial pneumothorax.

Influence of Diet on Nitrogen Balance—Hawks and her associates observed five children who received constant diets containing 3 Gm of protein per kilogram of weight. They all excreted the same proportion of the nitrogen intake but the urine figures fluctuated according to variations in the intake, while the feces values remained constant for each child and were proportional to the dry weight of the feces. The ratio of fecal nitrogen to dry matter consumed remained fairly constant for each child but varied between children according to the character of the stools. For individual children the coefficient of digestibility varied between 86 and 92.7 per cent while the retention values remained more constant but both values fluctuated in proportion to the period by period variation in the diet. Immediately following the change to a protein diet of 4 Gm the excretion values were irregular. After nine days they had apparently reached an equilibrium. The average of the retention and intake values per kilogram for all children for each separate period showed that the children retained nitrogen in relation to the period but with variations except immediately after the change in diet.

Inclusion Bleennorrhoea—Howard states that recent research indicates that inclusion bleennorrhoea is a specific, non-bacterial form of conjunctivitis due to a filtrable virus, apparently transmitted to the infant from the mother during passage through the birth canal. It appears from the fifth to the tenth day of life, and its course, while self limited, may extend over many months. Diagnosis can be established only by means of examination of Giemsa-stained preparations of the conjunctival secretions. Cultures are either sterile or show only the usual nonpathogenic conjunctival organisms. In the absence of a specific therapeutic agent, treatment should be symptomatic, with the prevention of secondary infection. Bacteriologic studies should be made in every case of ophthalmia neonatorum, however mild, and each examination should include a study of the exudate and conjunctival scrapings after special staining by the Giemsa method.

Diet in Children with Diabetes—Lichtenstein has been using the free diet for diabetic children for more than four years. By free diet he means a diet without any restrictions and without weighing the food or any of its ingredients. The only restriction in diet is to avoid luxury, which should be avoided also by healthy children. The insulin is given in doses sufficient to keep the child in good general condition, in good increase of weight and free from ketone bodies in the urine. The change from the restricted to the free diet generally takes place without any disturbances. As a result of the release from restrictions the children show signs of voracious hunger for carbohydrates. After some time however, they reduce the consumption of carbohydrates of their own accord. An inconvenience attached to the free diet seems to be that three injections of the usual insulin must be given in twenty-four hours, often in cases in which two injections were sufficient during the restricted diet. With protamine insulin it has been possible to reduce the insulin doses from three to two and in many cases to only one injection a day in spite of keeping the child on a free diet. Children who had earlier always shown decided positive reactions to the Gerhardt and Legal tests and who in many instances had to be admitted to the hospital again and again with threatening coma have been free from these difficulties after being placed on a free diet.

Bronchopulmonary Moniliasis—Farness believes that bronchopulmonary moniliasis, masking under the guise of tuberculosis occurs in all climates with much greater frequency than is generally recognized. The disease is amenable to treatment, making early diagnosis important. In the mild type the general condition of the patient is good and there is no fever. Frequent recurrence of slight, persistent cough with scanty, mucopurulent sputum without blood is the rule. Physical examination of the chest is negative or reveals only a few rales. In the moderate form the symptoms may simulate an early phthisis with continued low grade fever. The sputum is mucopurulent and tenacious and may contain blood. Symptoms may be continuous but are usually intermittent. Nutrition is affected to only a slight degree. A diagnosis of chronic bronchitis, bronchiectasis or bronchial asthma is usually made. In the severe form the disease runs a prolonged course with periods of exacerbation of symptoms. A history of recurrent attacks of 'pneumonia' is often elicited. The pulmonary involvement may be unilateral or bilateral. Roentgenologically the picture is that of pulmonary tuberculosis. There is the same hectic fever and night sweats with gradually developing emaciation and loss of strength. There are attacks of dyspnea and paroxysmal coughing, worse at night. The sputum is mucopurulent tenacious and often hemorrhagic and may have a yeasty or sweetish odor. Many cases follow pneumonia or influenza and some give a history of bronchial asthma several years prior to the onset of the disease. This suggests a lowered tissue resistance. The physical signs are those of patchy consolidation and fibrosis of purulent bronchitis and bronchiectasis and often of abscesses and cavities. Roentgenograms are not distinctive and simply reveal a pathologic process similar in appearance to other types of pulmonary infection. Sputum from a case of pulmonary infection which fails to reveal acid fast organisms and does contain yeastlike organisms, should be subjected to further mycologic studies. The responsible organism is of the genus *Monilia* belonging to the class of Hyphomycetes or fungi imperfecti. There are two methods for the differentiation of species: animal inoculation and sugar fermentation reactions. The prognosis is on the whole good. The mild type may result in spontaneous cure and is always readily amenable to specific therapy. The moderate type usually responds but often requires a prolonged course of treatment. The severe type may respond to treatment in its very early stages but is apparently incurable.

although it may be months before death supervenes. The iodides are regarded as specific. This is based on the specific germicidal effect of potassium iodide on *Monilia*. It is administered in large doses by the oral or intravenous route. A case is reported.

Tuberculosis of the Kidney—Hinman contends that the conception that renal tuberculosis is bilateral at onset, that in the majority one side heals spontaneously leaving a unilateral lesion and that occasionally both sides may so heal should have no effect on the management of clinical renal tuberculosis. This conception necessitates more than ever the differentiation of preclinical and other forms of tuberculosis of the kidney—such as military tuberculosis—from the clinical forms of the disease. The finding of pus and tubercle bacilli in the urine points definitely to the clinical form of renal tuberculosis, but the diagnosis is not complete until all possible associated lesions have been searched for and recognized. The routine use of retrograde pyelography is condemned, as it may aid in the spread of the infection. Worldwide experience demonstrates the superiority of nephrectomy in the treatment of unilateral tuberculosis of the kidney. When tuberculosis is localized in the kidney and the patient has been properly prepared nephrectomy is almost 100 per cent curative. When associated lesions exist in the bladder seminal tract or elsewhere, nephrectomy is still from 60 to 70 per cent curative. Nephrectomy is rarely an emergency procedure and should be performed only after a complete study and careful preparation. Clamping of the pedicle should be the first objective. As much of the ureter as is accessible should be removed but a complete ureterectomy is unnecessary.

Water Balance in Relation to Toxemias of Pregnancy—Davis states that normally the body maintains a balance of water by regulating the output to the intake. The intake of water may exceed the output in which case a positive water balance will be established. This may be due to an excessive consumption of fluid or to an interference with the output. Pregnancy normally is characterized by a positive water balance. This retention of water is most marked in the last half of the gestation. The generalized tendency to edema in pregnant women may be the cause or the effect of this positive water balance. The fetus may be regarded as a fast growing tissue of the mother's body consuming considerable water. The placenta likewise enlarges rapidly leading to marked retention

of fluid. The total water requirement of the mother may become disproportionate to the surface area. This permanent increased fluid supply, cellular and intracellular in character, is evidenced by the ease with which edema develops late in pregnancy. The blood volume gradually increases so that at term the total volume averages 23 per cent greater than in the nonpregnant individual. This blood volume increase is a blood dilution, for the increase in the hemoglobin and the cellular constituents does not keep pace with the increase in the blood plasma. This altered fluid metabolism of normal pregnancy necessary for both the growing fetus and the preparation for labor can be easily upset and result in pathologic complications of serious import. An increased positive water balance is thus a characteristic finding in most of the late toxemias of pregnancy. A decreased blood volume with a concentration of the cellular constituents is associated with severe preeclampsia and eclampsia. Negative water balance results when the available supply of water to the body diminishes below normal levels, either as a result of decreased intake or because of an interference with gastrointestinal absorption. Thus, starvation, vomiting and diarrhea result in an interference with the fluid intake. There may be an excessive loss of water so that the normal balance cannot be maintained. In severe cases of dehydration there is a decrease in the blood volume, with a resultant increase in hemoglobin, cell volume, serum protein and nonprotein nitrogen. Hyperemesis gravidarum is chiefly characterized by a negative water balance in which condition the available supply of water to the body tissues is decreased because of the continued vomiting. The late toxemias of pregnancy, preeclampsia and eclampsia are characterized by a marked disturbance of water balance. The normal positive water balance of pregnancy probably contributes to the ease with which a pathologic water balance develops. Clinically, the earliest manifestation of preeclampsia may be the sudden gain in weight. Whenever a patient gains from 3 to 4 kilograms (6½ to 9 pounds) in a week or ten days, one must assume that this increased weight represents to a large extent an increased water storage. Edema may or may not be present, depending on whether this fluid is largely intercellular or extracellular. With the retention of water there occurs a retention and storage of chlorides, for tissues cannot store water unless sufficient chlorides are present. The blood chlorides, however, fail to increase in amount even during the convulsive state, for a balance is always maintained between the blood chlorides and the tissue chlorides. This increased chloride content of the body tissues represents, therefore, an increased intake and retention of chlorides rather than a decrease in the chloride output. If one now carefully estimates the intake and the output of fluids, the increasing positive water balance is readily detected.

Healing of Empyema Cavities—Allison maintains that the classification of acute empyemas into the synpneumonic and the postpneumonic, and the recognition of the significance of these types have done much to reduce the immediate mortality from operation. Now the incidence of chronic empyema with its attendant morbidity and mortality should be reduced. To this end two groups, simple and complicated, are suggested. The simple empyema is one in which no permanent structural alteration has taken place within the lung tissue and in which, with adequate drainage, the lung expands completely to fill the chest with no deformity of the parietes. Such an empyema should always heal without difficulty. The complicated empyema is one in which structural damage has occurred in the lung to such an extent that complete reexpansion is impossible, and in those circumstances not only will there be delay in healing but this will occur partly at the expense of the parietes. The most significant point in the history is the relation of the febrile attack to the pleuritic pain. If the pleuritic pain occurs at the beginning of the illness the empyema is likely to be a simple one. If, however, a febrile attack is the initial disturbance, followed by pleuritic pain, the empyema is likely to be complicated. Streptococcal pneumonia and pneumonitis, secondary to lung abscess and bronchial block, start in the depths of the lung tissue and spread outward to the pleura by the interstitial lymphatics, so that pleurisy occurs at a later stage of the illness. In no case does preliminary aspiration do harm. It relieves the patient and at the same time gives valuable information to the operator. When a cavity is filled with large masses of fibrinous clot, aspiration is not always possible, but its routine attempt has been found to diminish the number of cases requiring secondary drainage operations. When empyemas have been drained without previous aspiration, it has sometimes been found that these adjustments result in the lung coming up flat against the end of the tube and so interfering with the drainage of a relatively deep space. Therefore before the point of drainage is decided it is an advantage to allow these immediate adjustments to be made by the aspiration of as much of the pus as possible followed by x-ray examination in two or more planes. It is desirable to know before operation the shape, position and size of a cavity after the pressure within it is relieved, the composition of the parietal wall and such information about the way in which the empyema will heal as may be deduced from consideration of its nature and the elasticity of its walls. To this end aspiration is done through a wide-bore cannula and when possible as much of the pus is removed as possible and then, by leaving the cannula in position while detaching it from the suction apparatus, a little air is allowed to be drawn into the cavity by the patient's own respiratory effort. The presence of air in an empyemic cavity is not harmful but by creating a fluid level it makes accurate x-ray examination of the cavity possible. Following aspiration, roentgenograms of the chest are taken from which the best point for drainage is chosen. The

method of drainage, open or closed, is not considered to be of any importance so long as the tube is large enough and in the right place. A portion of a rib is always resected.

- *Observations on Diagnostic and Prognostic Significance of Electrocardiograms Showing Anomalous Forms of QRS in Lead III Based on an Analysis and Follow Up Series of Cases A A F Peel—p 53

Electrocardiograms Showing Anomalous Forms of QRS in Lead 3—Peel reviewed 1873 electrocardiograms obtained from 1,307 patients during 1928 to 1933. Those showing anomalous forms of QRS, have been selected and classified into groups, and the patients in each group have been followed up and when possible reexamined during 1937. Many different types of QRS, have been encountered. The series of patients includes both hospital and private, ambulant and bedridden. All the more important varieties of cardiovascular disease were represented and in addition there were numerous "functional" cases, a number of patients suffering from disease other than cardiovascular, and a few who were thought to be malingering. The most important prognostic feature of these electrocardiograms is the breadth of the QRS complex. When the duration of the QRS complex at the first examination was below 0.08 second the mortality in the interval was 23 per cent. With a QRS duration of 0.08 second the mortality was 43 per cent. When the QRS duration exceeded 0.08 second at the first examination the mortality was 71 per cent.

Treatment of Stomatitis Caused by Diet Deficiency—Aykroyd and Krishnan present the results of giving eggs, soya bean and yeast autoclaved in an alkaline medium to children suffering from stomatitis. The patients given treatment were all boys of ages ranging from 8 to 16 years. Nearly all were living in boarding schools, and during the period the supplement was given they continued to consume the defective diets which had led to the development of stomatitis. Of seven boys treated with eggs, one egg daily for thirty-two days produced definite improvement in three but not complete disappearance of all signs. Two eggs were then given daily for twenty days, and complete cure resulted. The four boys who were given three eggs daily were cured in three weeks. Other pupils in the institutions on the same diet without the addition of eggs showed no improvement during the same period. Five patients received 1½ ounces (45 Gm) daily of soya bean for thirty-two days and 3 ounces (90 Gm) daily for thirty-two days. The beans were given whole being cooked until soft. No improvement was observed in any of the boys and one of them became worse. In the same period three boys in the same school were cured by eggs. Alkaline yeast autoclaved for five hours at 130 C at pH 9.2 and subsequently neutralized was given to eight boys the dose being one half ounce (15 Gm) daily.

Acute Intoxication from Ingestion of Aniline—Cathala and his associates report the case of a child, aged 18 months, in whom an acute intoxication resulted from the ingestion of a tincture with an aniline base. This case induced the authors to make experiments on rabbits. They studied the action of aniline on the alkali reserve, the blood chloride and sugar and the respiration. The authors reach the following conclusions: 1. Acute intoxication by aniline, in addition to the methemoglobinizing effects, produces profound changes in the acid-base equilibrium and the glycemic regulation. 2. The acute intoxication by aniline influences the nervous system and determines grave disturbances, such as asthenia, polypnea, somnolence and collapse. 3. It is interesting to note that in the young child a definite intoxication provokes symptoms which do not fundamentally differ from those which characterize the choleriform toxic syndrome.

Chemistry of Material Obtained by Sternal Puncture

—Benda and his associates report studies on the sugar content of the blood and of the marrow obtained by sternal puncture. In studies on twenty-five subjects they found that the glycomyelia is equal to or slightly less than the glycemia. In hyperglycemic states without glycosuria, the glycomyelia is extremely variable in comparison with the glycemia. This observation was made on nine patients. In diabetes, glycomyelia has a decided tendency to be higher than glycemia, this can be demonstrated only at times, namely if, taking into account the absence of chemical homogeneity in the medullary juice, the sugar content is determined in several successive specimens. The investigations on diabetes were made in five cases. The authors suggest that the study of glycomyelia be applied as a routine measure for the study of sugar metabolism (tests for insulin, epinephrine, phlorhizin and alimentary glycosuria).

Roentgenologic Visualization of Small Intestine

—Ghelen and Mengis say that the methods hitherto employed in the roentgenologic visualization of the small intestine have failed to give satisfactory results. Their aim was to avoid these difficulties. To avoid the pylorus they injected the opaque substance directly into the small intestine in a continuous stream. The examination is made on fasting patients who the evening

before have been given a laxative (castor oil or epsom salt). If this purge has been without effect, an enema is given before the examination. It is important that the large intestine is empty. A duodenal tube with an exterior diameter of 5 mm (interior 3 mm) is introduced. The entrance of air into this tube or sound is avoided by closing the external end by means of a forceps. Once the sound has reached the duodenum under roentgenologic control, 30 Gm of warm castor oil is injected and is eliminated completely from the tube by 30 cc of warm water, introduced immediately after. The patient rests for from forty-five to sixty minutes. Then a tube is connected with the duodenal sound. This tube is in communication with a container which is 1.5 meters above the patient's mouth and which holds 150 cc of thorium oxide and from 100 to 120 cc. of warm water. The patient is placed behind the fluoroscopic screen. The forceps is removed and the fluid flows in. If the patient feels distress he should breathe slowly and deeply, so as not to expel the sound. Usually after five or six minutes the opaque substance can be seen advancing rapidly in the small intestine. If the image appears clear, a film may be taken. After ten or fifteen minutes a second roentgenogram is made. At this time the liquid should have reached the ileum, often it is arrested for a time in the terminal portion of the ileum before it goes into the cecum. The fluid may be introduced while the patient is standing or reclining. The authors prefer the first position and have the patient assume the recumbent posture when the exposure is made. At this moment the patient is told to hold his breath and to retract the abdomen. If the patient is not fatigued, a little air may be introduced into the duodenal sound. This reaches the small intestine rapidly and allows a better outline.

*Hypochondriasis and Epilepsy R Hirsch—p 367
Cerebrolytic Capacity of Cerebrospinal Fluid P Buchler—p 375

Dementia Paralytica

—Schmuttermayer reports clinical and therapeutic experiences in 295 cases of dementia paralytica at the Psychiatric-Neurologic Clinic of Innsbruck. About 70 per cent were men and 30 per cent women. The predominance of dementia paralytica in males cannot be entirely explained as a result of a higher incidence of syphilis in men, for statistics have revealed that whereas the incidence of syphilis was only 20 per cent higher in men than that of paralysis was 130 or even 143 per cent higher. However several other factors have to be considered in connection with the sex incidence of dementia paralytica. The author stresses the rarity of the disease among farmers. Only 22.4 per cent of the cases had received specific treatment during the early stages of the disease and not one had been given treatments that were adequate according to present standards. Since in many cases it proved impossible to determine the time of infection, the periods of incubation can be estimated only approximately. More than 50 per cent of the patients had simple dementia, 85 per cent had the dull-euphoric form, 91 per cent had the expansive type, 34 per cent had a depressive type, 24 per cent a paranoid form. The author gives attention chiefly to malarial therapy, to which 263 of the patients were subjected. In evaluating the treatment, one should permit at least five years to elapse before making a final estimate. Treatment with recurrent fever was employed in a few cases and in these it was either preceded or followed by malarial therapy. Rat bite fever likewise was mostly employed as a secondary treatment. Its efficacy compared favorably with that of malarial therapy.

Hypochondriasis and Epilepsy

—Hirsch investigated whether relations exist between hypochondriasis and epilepsy. The prerequisites for the development of hypochondriasis are despondency, dependence on environmental conditions, selfishness, self criticism, vanity and cowardice. The author says that epileptic patients almost never exhibit hypochondriasis. The psychologic foundations of the two disorders are so different that the epileptic character excludes the development of a true hypochondriasis. Among 600 epileptic patients he did not find one who had a hypochondriac neurosis. He illustrates with case

histories that those who at times appeared hypochondriac did not have a hypochondriac neurosis in the true sense but were epileptic patients who exhibited hypochondriac signs only during depressive periods, the signs disappeared together with the depressions. He made all his studies on patients in institutions and suggests that those not in institutions and still socially adaptive might show different psychologic aspects.

Aplastic Myelosis Clinical and Anatomopathologic Study of Cases E. Samek —p. 331

Eosinophilia from Ingestion of Liver—Massobrio and Maranzana observed the eosinophils during liver treatment of twenty-five patients suffering from pernicious anemia and also in normal persons. The liver, almost raw or slightly boiled for thirty minutes, was administered with the diet in amounts of 250 Gm a day. The authors conclude that increased eosinophilia is induced in all patients who are suffering from pernicious anemia, as well as in normal persons, from ingestion of raw liver and in 80 per cent of the cases by ingestion of almost raw liver. It is not induced by ingestion of boiled liver and by the parenteral administration of injectable extracts of liver. Eosinophilia from the administration of liver is not an index to show the favorable effects of the liver treatment. It increases from overstimulation of the parenchyma of the marrow bone by substances of the liver, followed by a reaction of increased production of hemohistioblasts. Eosinophilia from administration of raw liver develops from the allergic action of proteins which are contained in liver and enter the blood in large amounts. It develops by chemotaxis. Splenectomy which was done in the course of administration of liver in dogs failed to induce increased eosinophilia.

Modifications of Blood from Irradiations of Spleen and Hypophysis—Segre gave rabbits roentgen irradiations to the spleen and to the hypophysis for fifteen minutes at a distance of 40 cm from the skin, at doses of 100 roentgens with a current of 3 milliamperes and 150 kilowatts through a filter of 0.5 mm of zinc and 2 mm of aluminum. He found that the irradiations cause diminution of the coagulation time, the bleeding time and the number of platelets during the first six hours, after which they slowly return to normal. Within the sixth and twelfth hours moderate erythropenia takes place, which in the course of twenty days returns to normal or to slight erythrocytosis after splenic irradiations and to slight erythrocytosis after hypophysial irradiations. Irradiations to the spleen are followed during the first few hours by oscillations of the number of leukocytes, which are followed by leukocytosis and relative or absolute pseudothrombophilia followed by relative or absolute lymphocytosis. The leukocytic formula remains normal in the largest number of cases after irradiations to the hypophysis. Irradiations to the spleen or to the hypophysis induce slight monocytosis. By the thirtieth day the morphology of the blood and the number of erythrocytes are normal. Erythroblasts may be present in the blood of some animals in the course of the treatment. Slightly increased poikilocytosis and polychromatophilia appear frequently after hypophysial irradiation.

*Influence of Exogenous Superinfection in Pathogenesis of Pulmonary Tuberculosis in Adults E. Filla —p. 177

*Variations of Sodium Chloride in Blood After Surgical Interventions F. De Lorenzo —p. 182

Exogenous Pulmonary Tuberculosis in Adults—Filla states that exogenous superinfection is a frequent cause of pulmonary tuberculosis in adults ranging in age from 15 to 25 years and rare after that. The disease shows typical early

tuberculous infiltration of Assmann's type. When the bacilli are virulent or the patients are in a state of receptivity, bronchopneumonic lesions which follow a serious evolution develop. Tubercle bacilli of exogenous or endogenous origin may remain for a long time in the body of a person with good immune biologic resistance, without causing tuberculosis, or causing only transient nontuberculous symptoms. The behavior of the large number of tubercle bacilli that enter the body from superinfection depends on the receptivity of the patient when superinfection takes place and for a long time after that, as the latent disease may develop as soon as infection becomes stronger than immunity. The dynamic energy of tuberculous infection or superinfection plays the most important part in the development of tuberculosis in children. For the development of the disease in adults, the individual factor plays the most important part.

Sodium Chloride in Blood After Surgical Intervention

—De Lorenzo found that after surgical intervention the amount of sodium chloride in the plasma and in the total blood diminishes in all cases, whereas it increases in the erythrocytes. The diminution is proportional to the gravity of the condition, the severity of the operation and the development of postoperative complications. It is unrelated to the type of anesthesia used and is caused by disturbance of the acid base equilibrium with consequent acidosis. Injections of hypertonic solution of sodium chloride reestablish the acid base equilibrium.

Treatment of Juvenile Obesity S. Schere —p. 42

Prevention of Measles—Bazan and Sujoy administered intramuscular injections of placental extract to 125 children. Satisfactory results were obtained in sixty-four of seventy-nine cases in which the treatment was administered for prevention of measles. The latter was greatly modified in fourteen of fifteen cases in which contagion occurred after administration of the injection. The treatment was given in the course of the disease in forty-six cases and the evolution of the disease was favorably modified in forty-three. The earlier the injections in relation to exposure to contagion and in the course of the disease the better the results obtained. The latter is harmless and does not induce reactions.

*Biologic Reaction for Gastric Cancer R. Redi and A. Continis —p. 475

Biologic Test for Gastric Cancer—Redi and Continis test consists in the injection into an inguinal lymph node of 1 cc of an extract prepared from cancerous gastric tissue with removal of the lymph node thirteen or eighteen days later for microscopic examination. The authors found that in patients suffering from cancer of the stomach the injections of a substance from extracts of normal stomach do not induce change in the lymph node, whereas the injected cancerous extract induces macroscopic and microscopic changes. In all cases the size of the lymph node is increased and there is tumoral infiltration of the node. The intranodular injection of either substance induces no reaction in normal persons. The authors believe that the test is specific for gastric cancer, which produces sensitizes the lymph node.

Electrocardiogram in Insulin and Metrazol Shock—Hadorn reports investigations which indicate that insulin hypoglycemia signifies a cardiac impairment. To what extent the cardiac damage is caused by insulin and to what extent by hypoglycemia has not been determined. Changes in the T wave of the electrocardiogram are generally ascribed to insulin, but since these are reversible, many authors do not regard them as a manifestation of myocardial impairment. He found that tachycardia and increased blood pressure often result from the insulin therapy of schizophrenia. They are elicited by the hypoglycemia and the reactive excretion of comparatively large amounts of epinephrine, but they usually disappear within a few hours. After mentioning the electrocardiographic changes in insulin hypoglycemia, the author says it cannot be denied that these changes signify either a cardiac lesion or a temporary impairment of the function. This implies that hypoglycemia should be avoided in cardiac impairment and that great caution is necessary in the administration of large doses of insulin. He made electrocardiographic studies also in metrazol shock. He found that metrazol shock therapy does not cause the same electrocardiographic changes as does the insulin shock, nevertheless it does cause changes, particularly in the auricular activity. The electrocardiograms that are made after metrazol shock reveal chiefly sinus tachycardias and a tendency to extrasystoles and auricular fibrillation. Changes in the S-T section and in the T wave which characterize insulin shock, are absent. The auricular fibrillation that results from metrazol treatment usually yields to quinine. In insulin shock therapy and also in metrazol shock therapy it is not yet possible to render a definite estimate about the possibility of a permanent cardiac and vascular impairment.

- Bacterium Pneumointes as Cause of Posttraumatic Meningitis H Heubach—p 271
- Etiology of Agranulocytosis C Bresgen—p 273

Hypovitaminosis and Osteomyelitis—Wachsmuth and Heinrich cite Takahashi's experiments on the pathogenesis of hematogenic infectious osteomyelitis. Takahashi demonstrated that the resistance toward bacterial infections is reduced when there is a deficiency of vitamins A, B and C. Metastases occurred in the long bones especially in C avitaminosis. Metastases in the bone marrow developed after intravenous administration of suspensions of staphylococci in 100 per cent of the avitaminotic animals but in only 44.4 per cent of the controls. The lack of vitamins, particularly of vitamin C, produces a locus minoris resistentiae at the end of the long bones so that they are especially subject to infection. This is understandable in view of the changes in the medullary structure observable in avitaminosis. Takahashi's experimental observations were corroborated by a clinical case observed by the authors. A man aged 24 acquired a streptococcal osteomyelitis following scarlet fever. Four months later the patient complained of pain in the arm and still later of pain in the right leg. Roentgenoscopy disclosed sequestration in both arms and legs. Besides a slight swelling there were no other clinical signs at the four sites of the osteomyelitic process. The sequestrums were removed and examination of the pus yielded hemolytic streptococci. Noteworthy is the symmetric involvement of both radii and both tibiae. The authors say that in view of a starvation diet, which the patient had undergone for five weeks, a hypovitaminosis

was present. Experimental and clinical observations indicate that disturbances in the vitamin metabolism may make the bone marrow more susceptible to infections. It may be concluded that hematogenic osteomyelitis is dependent on factors that hitherto were disregarded. When these factors are considered, surgical treatment alone is not sufficient. A suitable diet during infectious diseases may be a valuable aid in preventing metastases in the bone marrow.

Diagnosis of Dental Infection by Short Wave Provocation—Gutzeit directs attention to an earlier description of this method published in the *Munchener medizinische Wochenschrift* (84 961 [June 18] 1937 abstr THE JOURNAL Aug 14, 1937 p 543) and then describes further experiences which again revealed the following factors. 1 Short wave irradiation of healthy teeth with living dental pulps does not cause a general reaction that becomes manifest in an acceleration of the sedimentation speed of the erythrocytes. 2 Some of the teeth that have granulomas or the pulp of which is dead or diseased show, after short wave irradiation, a noticeable general reaction which is indicated by an acceleration of the sedimentation speed. 3 However, in some of the teeth, which roentgenoscopy has revealed as diseased, short wave irradiation does not result in an acceleration of the sedimentation speed. These observations indicate that, whereas the irradiation of healthy teeth produces no general reaction, there are some diseased teeth which do produce a reaction and other diseased teeth which do not. The author concludes that those diseased teeth which as the result of short wave irradiation cause an acceleration of the sedimentation speed exert an unfavorable effect on the organism. In case of a negative outcome of the short wave provocation of diseased teeth, two possibilities must be considered: either the tooth under observation contains no toxic substances and has no connection with the lymph and blood vessels of the general organism, or the method of short wave irradiation may have been faulty. The author deplors that such methodical errors cannot be entirely avoided with the present equipment. Discussing the value of the short wave provocation, he says that extraction of the teeth which gave a positive reaction did not always produce improvement in the general condition, if the lymph nodes have already become infected, or if new foci have already developed in other parts of the organism, the removal of the primary focus would not counteract these secondary foci. Nevertheless, if it is used with care and if methodical errors can be avoided, it is a valuable diagnostic aid.

Pneumothorax in Pulmonary Abscess—After citing various treatments suggested for pulmonary abscess, Kollmeier says that pneumothorax therapy is advised by few owing to the fact that the dangers of this method are frequently stressed. It is pointed out that pneumothorax therapy in pulmonary abscess readily leads to an involvement of the pleura and to empyema. Pneumothorax therapy of pulmonary abscess was used as early as 1833, long before pneumothorax was introduced into the treatment of pulmonary tuberculosis. The author resorted to pneumothorax therapy in seven of ten cases of pulmonary abscess that came under his observation. In all except one of the cases the abscess was either in a central location or near the hilus. He thinks that this localization of the abscesses was chiefly responsible for the especially favorable action of the pneumothorax therapy. Involvement of the pleura was observed in none of the cases. After the pneumothorax was induced there always was an improvement in the general condition and in some cases the cough and expectoration disappeared. Moreover, the fever usually decreased and the appetite improved. Only small quantities of air should be introduced. The pressure should remain negative, at any rate, no great pressure should be exerted on the lung. Refilling should be

continued until the fever has subsided and cough and expectoration have disappeared. Pneumothorax is indicated in abscesses with a central or juxtahilar location, but in juxtapleural abscesses it should be used with the greatest caution or not at all.

Anastomoses Between Bile Ducts and Gastrointestinal Tract—Talman reports a study of sixty-five cases of anastomosis between the bile ducts and the gastrointestinal tract performed at the Feodorov Surgical Clinic of the Military Medical Academy, Leningrad, between 1905 and 1935. The operation was performed in twenty-five cases because of a malignant tumor, while in thirty-nine the condition was benign. There were seventeen cholecystogastrostomies, fifteen cholecystoduodenostomies, eight cholecystojejunostomies, two choledochogastrostomies, twenty-one choledochoduodenostomies and two hepaticholangioenterostomies. He believes that cholecystogastrostomy for the treatment of gastric ulcer has not justified itself. It is apparent from several clinical studies that reduction of the gastric acidity is not accomplished either because the amount of bile necessary for the reduction is not adequate or because of the stimulating effect of bile on the gastric juice secretion. Other objections are the chronic infection of the gallbladder which invariably takes place and the regurgitation of the gastric contents into the bladder and in some cases into the bile tracts. The advantages of choledochoduodenostomy are offset by the fault that it permits the entrance of the gastric and duodenal contents into the intrahepatic bile channels. His studies established that this occurred in sixteen of twenty-five cases studied. The follow-up study further demonstrated that in many cases this condition does not lead to an acute infection of the biliary tracts, while in others it gives rise to attacks of cholangitis with colic, chills, fever, jaundice and, in a few cases, liver abscess. Many of these patients have chronic cholangitis which however does not give rise to severe flare ups and to significant symptoms. The author concludes that formation of anastomosis between the bile ducts and the gastrointestinal tract represents a crude mechanical interference with the complicated biliary system and its many functions. It is indicated only in cases of obstructive jaundice caused primarily by a malignant neoplasm and in certain benign lesions capable of producing grave disease states.

Motor Function of Stomach After Resection—Vitkin presents a study of seventy-four patients in whom partial gastric resection was performed. The type of operation was the second method of Billroth in sixty-seven and the Polya-Reichel modification in seven. There were ten subtotal resections. Each patient was examined before the operation as to the gastric secretion, the presence of occult blood in the feces, the blood

picture, the roentgenoscopic appearance of the stomach with particular attention to its motor function, the size of the stomach, its motility, tonus and peristalsis, the emptying and the relief of the gastric mucosa. Similar observations were made after the operation at periods varying from two weeks to six years. Thirty-eight patients were examined from two to five times after the operation. Altogether there were 132 roentgenologic examinations on a stomach after resection. The author found that the stomach empties rhythmically after the second Billroth operation or after one of its modifications. He believes that it is not necessary to resort to complicated methods (Finsterer or Goetze) to accomplish the rhythmic emptying. The rhythmicity of emptying apparently does not depend on the extent of stomach removed, as it was in evidence after a subtotal resection. There are no data which speak in favor of formation of a sphincter in the region of the anastomosis. He feels that it is entirely unlikely after a resection according to the second method of Billroth. The periodic closure and opening of the anastomotic stoma is due to the peristaltic contractions and dilations of the nearest loop of the efferent limb of the bowel. Spasm of the anastomotic stoma after resection for a malignant condition is an early sign of a local recurrence. The majority of the patients have a hyperplastic gastritis which as a rule does not give rise to subjective sensations. The rhythmic emptying of the stomach after resection according to the second method of Billroth or its modification is paralleled by the excellent state of the health of the patients.

*Polyneuritis of Pregnancy and Korsakoff's Psychosis P A Van der Hoeven—p 873

Liver Therapy in Hypochromic Anemia—De Jong emphasizes that liver therapy remains the treatment for hyperchromic anemia, that is, for those anemias in which the color index is above 1. He deplors the fact that it is often indiscriminately used in other forms of anemia and points out that Castle and Minot warned against this by emphasizing that the time to establish the exact diagnosis in anemia is before treatment is begun, not after the blood picture has been obscured by indiscriminate medication. He shows that in hypochromic anemia medication with iron and not with liver is advisable. In cases in which iron therapy does not counteract the hypochromic anemia the factor responsible for this failure should be investigated. If carcinoma, bleeding ulcer and polyps of the intestinal tract, or conditions like hypothyroidism, tuberculosis and chronic nephritis can be excluded, and still the response to iron is not adequate, liver may be tried in addition to the iron, but such cases are comparatively rare.

Polyneuritis of Pregnancy and Korsakoff's Psychosis—Van der Hoeven describes the history of a woman, aged 30 who for years had exophthalmic goiter. In June 1936 she became pregnant and emesis set in which soon assumed the character of hyperemesis. The patient was hospitalized and her condition improved so she was able to take food. However, psychic disturbances set in and later the hyperemesis recurred. In view of her poor condition it was decided to interrupt the pregnancy. At first there was improvement but the psychic disorder became more severe and the typical signs of Korsakoff's psychosis appeared. Moreover, the patient complained of severe pains in her arms and legs accompanied by formication and severe sweating. Examination revealed reduced strength of the muscles and abolishment of the tendon reflexes. A diet with high vitamin content produced some improvement but because of persisting parietic conditions hypesthesia and other disorders medication with a vitamin B preparation was begun. Under the influence of this treatment the disturbances gradually subsided. This clinical picture he believes results from a deficiency in vitamin B. Further, the induced abortion is a factor in the development of the picture. He suggests that B avitaminosis might play a part in the development of hyperemesis gravidarum.

ENDOCRINOLOGY AND THE UNDER- STANDING AND TREATMENT OF THE EXCEPTIONAL CHILD

LOUIS A LURIE MD

Director of the Child Guidance Home and Assistant Professor of
Psychiatry University of Cincinnati College of Medicine

CINCINNATI

The trend at present in child guidance work is apparently toward the psychologic or, more specifically, toward the psychoanalytic interpretation of behavior disorders in children. A glance at the literature on the subject of orthogenics is more than sufficient to convince the most skeptical that the problems of maladjusted, unadjusted, antisocial and asocial children are apparently all on the basis of emotional conflicts—conflicts due to infantile fixations, sexual repressions, maternal rejections and sibling rivalry. Apparently, human behavior can be explained only in terms of suppressions, frustrations, rejections, identifications, feelings of hostility, feelings of inferiority and inadequacy and the like.

That these conflicts are potent and frequent factors in the causation of abnormal behavior no one can deny, neither will any one deny that the psychologic approach to the study of human behavior has been fruitful of great results. On the other hand it must also be admitted that not all human reactions are merely conditioned emotional responses. Many reactions are conditioned by other factors such as somatic, endocrine and neurologic conditions. Organic factors may and do have a vital part in producing types of behavior that are inefficient, inadequate and abnormal.

The environmentalist, with his social approach to the study of the problem child, was the first to supplant the organicist, and now he in turn is being supplanted by the psychologist and the psychoanalyst. Each one, as he supplants the other, does not deny him entirely but nevertheless relegates him to a minor position.

Is such an attitude the proper one? Is this the path which persons entrusted with child guidance should follow?

If one pauses for a moment and defines what is meant by human behavior, one soon realizes that the answer to these questions must be in the negative.

Human behavior is the resultant of the interaction between the individual and his environment. In the words of Herbert Spencer, "Life is the adjustment of man to outer relations." This constant adjustment and readjustment is the process of living. Life

expresses itself in conduct or behavior, hence, if one is to understand human behavior either in its normal or in its abnormal phases, one must study in detail both the individual and his environment. Furthermore, it must be realized that man is more than a biologic organism, he is also a social being, growing and adapting himself to a specific environment. Hence, fully to understand human behavior one must study the individual as a psychophysical organism that is attempting to adjust to a specific environment. This is what is meant by the psychobiologic approach to the study of human behavior.

When such a well rounded approach is employed, rather surprising facts regarding the relative frequency of organic, psychologic and environmental factors in the causation of behavior disorders are elicited.

For example, the statistics of the Child Guidance Home in Cincinnati show that in 49 per cent of the cases of behavior disorders studied the underlying causative factors were found to be endogenous, or psychophysical, in origin. In only 23 per cent of the cases were the causes exogenous, or environmental. In the remaining 28 per cent, both endogenous and exogenous factors were responsible for the behavior difficulties.

Furthermore in approximately 75 per cent of the cases in the endogenous group the causes were organic. Psychologic factors as the primary cause constituted only a relatively small percentage. This finding is of especial importance in view of the present tendency to stress the psychologic approach in the study of behavior disorders in children.

The successful child guider is he who understands that the total integrated personality is a composite of the totality of the individual, that is, soma and psyche, plus the totality of the environmental situation. In other words, the molding of the personality is the resultant of the interactions of two dynamic systems, namely, a psychologic organism and a socio-economic physicochemical environment, working conjointly to produce in the child a type of reaction that gives him his distinctive personality. These two dynamic systems are composed of numerous separate component parts, each of which is capable of changing or modifying the personality. It is hardly necessary to point out the effect of climate, geographic location, economic status and many other environmental factors on the personality. Likewise every physician is acquainted with the devastating effects of such diseases as encephalitis on the personality make-up. Furthermore, the work of Stockard Kretschmer and others has demonstrated that certain patterns of abnormal behavior may conform with certain types of physical structure or constitution. Similarly the endocrine glands have their part in the determination of the pattern types of behavior.

Read at the Fourth Institute on the Exceptional Child, New Contributions of Science to the Exceptional Child, held under the auspices of the Child Research Clinic of the Woods School, Langhorne, Pa., Oct. 26, 1937.

An analysis of the first thousand cases of behavior disorders in children studied at the Child Guidance Home in Cincinnati showed that endocrine disturbances of various types and degrees of severity were present in approximately 20 per cent. In approximately 10 per cent of the cases the glandular disturbances were the principal causative factors. In other words, in about 100 cases of this series there was apparently a direct etiologic relationship between the endocrinopathy and the behavior difficulty presented by the child. For this reason, as far back as 1927, I said that "no examination of a problem child can be considered complete unless a careful endocrine study has been included."¹

Why such a study is essential is readily understandable when one realizes the importance of the glands of internal secretion in the growth and development of the child. The influence of the endocrine glands starts, in fact, long before birth. The potentialities which the infant brings into the world have in a large measure been developed as a result of hormonal influence on the fetus in utero.

It is safe to say that hardly a single bodily function is not directly or indirectly influenced by these glands. They are concerned with differentiation of tissue, with nutrition and growth, with sexual activity and with mental development. In brief they are bound up with all development, physical as well as mental.

Gigantism and dwarfism are the results of opposite extremes of functioning of the pituitary gland. Sexual infantilism may be due to deficiency in the secretion of the sex hormone of the same gland. On the other hand, this condition may be produced through failure of function of the sex glands themselves. Every gland of internal secretion, as a result either of overactivity or of underactivity, can modify the growth and functioning of the various tissues and organs of the body.

When one attempts to correlate specific forms of endocrine disorders with definite types of personality disturbances, it is essential to clarify the situation by first recognizing that the effects of endocrine dysfunction on the personality are of two kinds. The effects may be classified as (1) direct and (2) indirect.

It is well known that the mental retardation of the cretin is due to lack of thyroid hormone. Hypoparathyroidism may lead to great irritability, restlessness, emotional instability and even to a hypomaniac state, while the opposite condition, hyperparathyroidism, may lead to sluggishness, a depressed emotional state and great mental apathy. In conditions of hyperinsulinism, mental symptoms are frequently present. These may vary from vague neurotic complaints to mild psychotic manifestations. They represent the direct effects of the endocrine dysfunction on the personality.

In addition to the effects just described, there may be indirect effects. These include the mental attitude that the child adopts toward the physical abnormality produced by the glandular malfunction. The abnormality often produces emotional conflicts of great severity, with resultant marked personality changes and abnormal behavior.

The indirect effects are of tremendous significance, as they often determine the child's outlook on life and furnish the motif for his behavior.

If one bears this in mind it is not difficult to understand why the adolescent boy who is suffering from

eunuchoidism as a result of gonadal insufficiency should have a marked feeling of inferiority, which in turn leads him to shun his companions, to become morose and gradually to withdraw from the world of reality and live in a world of fantasy. For the same reason the girl whose face is disfigured because of a growth of coarse hair as a result of an adrenocortical involvement may become so intensely self conscious and morbid that she attempts suicide.

One must recognize not only the effects of hormone dysfunction on the mood, thought and behavior but also the reactions of the child to the knowledge that he is suffering from a disturbed bodily function. The former constitute the direct effects, the latter the indirect effects. Some children may show only one type of disturbance or effect, but most often both types are present.

The failure to distinguish between the direct and the indirect effects of the endocrine dysfunction on the mental and emotional make-up has led to considerable confusion in thought regarding the specificity of the correlations between endocrinopathic states and personality and behavior disturbances. As will be shown later, certain broad changes in the personality accompany pituitary disorders as well as other endocrine disturbances with such regularity that they must perforce be looked on as causally related. The clinical picture presented in such cases may vary, however, because of the varying intensity of the indirect effects of the endocrine dysfunction which may be superimposed on the direct effects. The former may be looked on as the subjective effect on the child of the knowledge of his incapacity or infirmity. Obviously, this will vary with each child and will depend largely on his native or constitutional endowment on his past experiences and on his social milieu. The indirect effects lead to a feeling of inferiority in the true adlerian meaning of the term. To what extent the organic inferiority will develop and what mental mechanisms may be produced as a result can be predicted only when the totality of the situation is known.

The personality is often profoundly altered by physical deformities. The tendency toward self pity that so readily develops may lead to introversion, to withdrawal from the realities of life and to neurotic manifestations.

On the other hand, the personality may be modified along definitely antisocial lines. Incurability, delinquency and even criminality may be the "end results of interference with the normal development of the ego instinct of the personality."

Obviously, it is impossible in a paper of this nature to discuss in detail all the various endocrinopathies as they may affect the personality make up and the ability of the child to make normal progress educationally, socially and emotionally. However, I do wish to describe some of the commoner forms of glandular disturbances that exceptional children may present.

One of the best known members of the endocrine fraternity is the thyroid gland. The structure and the functions of this gland have long been known to scientists. Especially well known has been the relationship of thyroid deficiency to mental retardation. The degree of mental retardation depends on the degree of thyroid deficiency, the greater the deficiency in the thyroid secretion, the greater the degree of mental retardation. This relationship is exemplified in cretinism and in myxedema in children. The literature con-

¹ Lurie, L. A. The Relation of Endocrinopathic States to Conduct Disorders of Children. *Am. J. Psychiat.* 9: 285 (Sept.) 1929.

tains many reports of marked improvement in the intellectual status as a result of thyroid medication. These conditions are as a rule not difficult to recognize, because when the mental impairment is severe the impairment in physical growth and development is so marked that the diagnosis is readily made. However, cases of such severe deficiency are, fortunately, relatively few in number and hence are not of very vital concern. It is the milder forms of hypothyroidism, forms in which the symptoms of thyroid deficiency are not so evident, that merit study, both because they are so numerous and because they are so easily corrected once they are recognized. What teacher has not come in contact with the child who is slow thinking and irritable, shows some form of speech defect, does not respond to the usual form of classroom discipline and is a school failure? Such children merit an endocrine examination because often they are suffering from varying degrees of thyroid deficiency.

In this connection I wish to call attention to a clinical syndrome in which extreme motor restlessness, destructiveness and speech disturbance are the outstanding symptoms. This triad of symptoms when present in young children almost always indicates a state of hypothyroidism. The child is very restless. Often the restlessness is so marked that he has to be forcibly restrained. He is careless with his possessions to the point of destructiveness. The complaint, however, for which most often the physician is consulted is that he shows some form of speech involvement, an involvement that may range from inability to pronounce certain letters and sounds to speech blocking and even to complete inability to speak.

The following two brief case reports illustrate this clinical syndrome.

CASE 1—J W F, a white boy, aged 5 referred for examination because of a marked speech defect according to the history had had a normal birth. He teethed and walked at the normal time. Talking, however, was markedly delayed, and even at the age of 5 he was difficult to understand. He was irritable and exhibited severe temper tantrums, especially when he was not understood. Destructiveness was not an outstanding characteristic, although he was careless with his toys.

On examination it was found that the child was unable to pronounce the letters C, K, J and S as well as all the linguals. His intelligence quotient as determined by the Stanford revision of the Binet Simon test was 120. The endocrine examination showed that he was suffering from mild hypothyroidism. As a result he was given thyroid extract. He responded nicely to the therapy. Not only did the speech defect disappear but also the purely physical symptoms, such as the delayed bone growth and the hypotonus.

In this connection I want to emphasize especially that seldom do clinicians associate restlessness with hypothyroidism. We usually think of restlessness as a symptom of hyperthyroidism. In children, however, hypothyroidism may have as one of its outstanding symptoms a severe form of restlessness, and the other two symptoms named are generally associated with it.

The parents were cautioned not to permit the child to attend kindergarten. Rather, they were advised to wait until he had completely overcome the speech defect before having him enter school. The reason for this advice was that children who enter school while suffering from a speech defect are apt to acquire a feeling of inferiority both because they become conscious of their handicap and because the other children ridicule them. When a feeling of inferiority develops, other

speech difficulties enter into the problem and make the cure very difficult. This particular child did not attend kindergarten but entered the first grade of school free from all speech impediments.

CASE 2—J D, a white boy, aged 4, referred for examination because he did not speak, according to his history had had a normal birth. His development, however, was markedly delayed. He did not teeth until he was 12 months old and did not walk until he was 20 months old. He first began to utter sounds at the age of 2½ years. He was very nervous and sucked his thumb, and there was a constant drooling of saliva. He was extremely restless, even in his sleep. At times he apparently would deliberately bump his head against the table chairs or wall. This occurred especially when he was excited. He fought constantly with every one and particularly with his younger brother. He was also very destructive.

Endocrine examination revealed the fact that the boy was suffering from severe hypothyroidism. There was no evidence of any organic involvement of the central nervous system (I mention that in passing because the developmental history would tend to indicate some trauma at birth. However, careful neurologic examination failed to reveal any evidence of such injury.) A psychometric test could not be made because the child was uncooperative.

The child was given appropriate glandular therapy and soon began to show a slow but steady physical and mental improvement. Today, at the age of 7, he speaks fluently and has been entered in a special school. His intelligence quotient is 85.

These cases are two examples of the triad of clinical symptoms—motor restlessness, destructiveness and speech defects as evidence of hypothyroidism, and in a number of such cases there has been improvement in the ability to speak as well as in the other symptoms as a result of appropriate glandular therapy.

Although the thyroid gland is the best known of the endocrine glands, today the pituitary gland is receiving the most attention. It has been called, and I think justly so, the "master gland" of the body. It not only secretes many hormones that are of vital importance to the growth and development of the body but also secretes substances that either initiate the activity of other ductless glands or stimulate other glands to greater activity.

By far the commonest form of pituitary disturbance in children is the so-called Froelich's dystrophy, or dystrophia adiposogenitalis. This condition may originate during childhood or adolescence and is of especial interest from the psychologic and psychiatric standpoints because of the distinctive personality characteristics and types of behavior with which it is frequently associated.

Allan Rowe² found that of sixty-eight children suffering from endocrinopathies associated with behavior disorders fifty-three showed pituitary dysfunction. In a similar study at the Child Guidance Home,³ I showed that pituitary disorders also constituted the dominant majority.

The true Froelich's syndrome is characterized by a triad of symptoms, namely, dwarfism, genital infantilism and adiposity of the mons-mammary girdle type. In other words, the fat is distributed principally on the breasts, abdomen and hips. Such children are small, fat and fair and have a distinctive personality make-up. They are as a rule cheerful happy and apparently contented their dispositions fitting in with the universal belief that fat boys and girls as well as fat adults are

² Rowe, Allan W. A Possible Endocrine Factor in the Behavior Problems of the Young. *Am J Orthopsychiat* 1: 451 (Oct) 1931.
³ Lurie, L. A. Endocrinology and Behavior Disorders of Children. *Am J Orthopsychiat* 5: 141 (April) 1935.

jolly, good natured and well behaved. Their reactions are slow, and hence they may be irritating and annoying to persons who feel that their slowness of response is indicative either of lack of interest or of carelessness. In fact, such children, because of their slowness, may give the impression that they are mentally retarded, whereas in the majority of cases the opposite is true. David Levy⁴ reported that in a series of thirty-three cases of Froelich's dystrophy, studied at the Institute for Child Guidance, only five boys were below the average in intelligence while seventeen were in the superior group. This was a predominantly higher score than that for the entire series of patients at the Institute for Child Guidance, for which there is a median intelligence quotient of 99.

At this point I should like to call attention to the fact that when a child is given a psychometric test he is required not only to answer the questions correctly but also to answer them in a reasonable length of time. In other words, not only correctness but also quickness of response is essential in order to obtain a good score.

Children with hypopituitary disturbances of the Froelich type are at a disadvantage in such tests. While their native intellectual ability may be normal, they may fail to answer many of the test questions in the prescribed length of time because of their longer reaction time and hence slower reactions. In other words, while they may be unable to solve in one minute the problem "If two pencils cost 5 cents, how many pencils can you buy for 50 cents?" they can solve it if given another minute or two. Nevertheless, their intelligence quotient suffers and they may be rated as subnormal intellectually or even as mentally defective. Such children often exasperate their parents and teachers because of their inability to learn. The teacher is confident that the child can learn if he only will but she will add mournfully that "it requires the explosion of a ton of dynamite under him to make him get a move on himself." Characteristically, after the explosion of dynamite, the child falls back smilingly into his usual calm, phlegmatic mode of life. It is important to recognize that this characteristic is on a hormonal basis. The sluggishness and long reaction time are not due primarily to the overweight but probably to the fact that the pituitary deficiency results in secondary hypothyroidism. It has been estimated that in hypopituitarism the basal metabolic rate may be lowered as much as 16 per cent. The implications regarding therapy in such cases are therefore obvious.

Another characteristic of these children is that they fall asleep readily and are difficult to arouse in the morning. Often they fall asleep in the classroom, much to the dismay and annoyance of the teacher, who attributes this symptom also to carelessness and indifference rather than to a lack of pituitary secretion.

From the behavioristic standpoint, children presenting the Froelich syndrome can be classified as belonging to the submissive-compliant type. Their lack of aggressiveness is outstanding. They are shy, gentle, easy going, timid and artistic, traits that are usually considered effeminate and which are in harmony with their physical appearance. This is especially noticeable in the case of boys who, because of the broad pelvis, rounded figure, fair smooth skin and rosy cheeks, high-pitched voice and absence of hair on the face and lips, have a distinctly feminine appearance.

As aptly stated by David Levy, "Their social adaptation to life is in the main one of easy compliance and submissiveness." They avoid strenuous physical exercise and the stress and strain of competitive work and sports. They prefer the arts to the sciences.

Their patterns of reaction and personality traits are due to the hormonal deficiency and can be looked on as the direct effects of the pituitary endocrinopathy on the personality.

In contrast to the submissive, compliant personality make-up of children suffering from Froelich's dystrophy is the aggressive, dominant make-up of children with the Loran-Levy type of pituitary dystrophy. In the latter type there are dwarfism and genital infantilism without adiposity. Children suffering from this form of hypopituitarism are as a rule mentally alert. They are forward and aggressive and tend to dominate their environment. They usually capitalize on their infirmity.

The direct effects of the hormonal pituitary deficiency on the child's personality may be intensified or altered as a result of the reaction of the child himself to his own deficiencies in growth and structure. These are the indirect effects and may far overshadow the direct effects of the endocrinopathy. Thus the child who, as a result of the pituitary deficiency, has a submissive, passive, phlegmatic personality may become aggressive, dominant and antisocial because of a feeling of resentment acquired as a result of the knowledge of his structural defects. Passivity, overdependence and submissiveness may be replaced by aggressiveness, truculence and independence, even to the point of delinquency and criminality. Such changes represent attempts to soothe the wounded ego as well as compensation for feelings of inadequacy. On the other hand, the feelings of inadequacy and inferiority, instead of calling out such compensatory mechanisms, may further heighten the submissive-passive type of behavior and make the child more and more dependent on others and therefore less and less able to make normal social adjustments.

How a child will react to his own infirmity will depend largely on the conditioning influences of his environment as well as on his life experience. Hence no two subjects need react alike. One girl may assume a role of careless indifference to the scoffing comments of her friends regarding her overweight and shape, another, because of the same condition, may withdraw completely into herself and find refuge from the jeers of her playmates in a life of fantasy, reverie and neurosis, while still another may attempt suicide. Similarly, the fat boy with the fair skin, the high pitched voice and the small genital organs may become so timid and fearful as a result of the taunts and jeers of his playmates that a shut-in type of personality develops and he refuses to make normal social contacts, or he may resort to bribery, trying by means of candy, treats to the movies and the like to get into the good graces of the gang and thereby stop the constant allusions to his infirmity. Many a youngster has resorted to stealing and has become delinquent in order to carry out such a plan. On the other hand the child, instead of withdrawing into himself or attempting to curry favor through bribery, may become anti-social. Feelings of hostility against society may develop because of the hurt his ego has suffered and he will replace the passive-submissive personality which the hypopituitary condition has instilled on him with a

⁴ Levy, D. M. Aggressive-Submissive Behavior and the Froelich Syndrome. *Arch. Neurol. & Psychiat.* 36: 91 (Nov.) 1956.

aggressive-sadistic attitude that will make him attempt to get even with the world

Therefore it is important to remember that the kind of personality disturbance that may be produced in a child suffering from a pituitary deficiency will depend not only on the direct effects of the endocrine disturbance, which are fairly uniform, but on the severity of the indirect effects on the personality produced as a result of the reaction of the total personality to the abnormality in its own structure and growth

Many kinds of combinations are possible, and it is highly essential from the standpoint both of diagnosis and of therapy to determine the relative importance of the two factors

The following brief case reports are presented to illustrate the foregoing statements

CASE 3—M M, a white girl, aged 16, referred for examination because of a complete change in her personality make-up had apparently always been a perfectly normal girl who had never caused her parents any concern. Her social adjustments and academic progress were all that could be desired. For the past year and a half, however, there had been a marked change both at home and at school. She had become listless and apathetic, was unwilling to exert herself and although tractable, showed no initiative. She appeared mentally dull, and it was only as a result of attending summer school that she was able to pass the third grade at high school. Coincident with these mental and emotional changes there was a rapid and tremendous gain in weight. The menstrual periods had become irregular, from three to four months elapsing between periods. The girl was very conscious of her overweight and refused to go in swimming or to associate with her former friends. Her only companion was another girl who was also markedly overweight. She was careless of her personal appearance. Another outstanding and disturbing symptom was an unusual degree of sleepiness. The girl slept from ten to fourteen hours every night and at times twenty hours. Often she would fall asleep in the classroom.

At examination she was seen to be tall and very obese. The excessive amount of fat had the typical girdle type distribution. The endocrine examination pointed to an involvement of the pituitary gland, with secondary involvement of the gonads and the thyroid gland. Appropriate glandular therapy was prescribed, with resultant improvement in both the physical and the mental symptoms. Weight was lost, menstruation became regular, the tendency to drowsiness disappeared and the girl again became the bright alert person she had formerly been. As a result of the loss in weight she lost her feeling of inferiority and resumed her normal social contacts.

This case brings out clearly both the direct and the indirect effects of a glandular disturbance. The direct effects of the deficiency in the pituitary secretion were marked overweight, drowsiness and sleepiness, menstrual irregularity, listlessness and mental sluggishness. The indirect effects were the development of a feeling of self-consciousness and inferiority which led the girl to shun her friends, to avoid social contacts and to evade those activities, such as swimming, that might bring her defects before the public gaze. With the restoration of the function of the pituitary gland to normal, there was a return to normality in the girl's physical, mental and emotional make-up.

CASE 4—D R, a white boy, aged 16, referred for examination because of the poor and indifferent work which he had been doing at school for several years. He was in the second grade of high school but had managed to get there only by dint of constant special tutoring. Both the principal and the teachers attributed his difficulties at school to lack of interest and concentration. Whenever the father blew him up, there was an improvement in the boy's school work. This improvement, however, was short lived.

According to the history the boy was fairly tractable but was sullen and resentful of authority. It seemed difficult for him to exert himself either physically or mentally. At home he appeared even more sluggish and apathetic than at school. He had a huge appetite and thirst and was especially fond of sweets. He fell asleep readily, and it was difficult to arouse him in the morning. The boy himself admitted the truth of all the charges. In his defense he submitted the statement that he was unable to concentrate for more than ten minutes at a time. He had first noticed this condition when he was in the fifth grade of school. Since then it had become increasingly worse. He claimed that he always tried his best but that when he found that he was not making any headway he lost interest in his school work. In fact, he lost all of his ambition.

Examination revealed that this boy was suffering from the adolescent type of Froelich's dystrophy. As a result he was obese, sexually underdeveloped and mentally and physically sluggish. When tested by the Stanford revision of the Binet-Simon tests he received an intelligence quotient of 85. This rated him as subnormal intellectually. The psychologist stated that his reaction time was unusually long.

This boy has been under treatment for the past year and a half. During this time he has received glandular therapy, to which he has responded nicely. He has fully matured sexually and in addition has become more alert mentally and physically. So far this year there has been no necessity for special tutoring in school. Another psychometric examination has not been made because it is felt that not enough time has elapsed since the first examination for the boy to have completely forgotten the original test questions.

Here is a boy whose adaptation to school, and to his home and hence to life had become very difficult primarily because of an insufficiency of the secretion of the pituitary gland. To many a psychologist an intelligence quotient of 85 would be sufficient explanation for his inability to make normal academic progress. However, this intelligence quotient did not truly represent the boy's intellectual capacity. The same lack of hormonal deficiency that caused him to be overweight and underdeveloped sexually caused him to be apathetic and mentally sluggish and therefore to have a long reaction time. This was reflected in his inability to answer the Binet-Simon test questions in the required length of time, which lowered his mental age and his intelligence quotient.

CASE 5—G B, a white boy, aged 15 years and 6 months, was referred for examination by the juvenile court because he had stolen money repeatedly from his parents, relatives and friends. The stealing had been going on for the past six years becoming more and more pronounced as the boy grew older. All forms of disciplinary measures had been of no avail. Persuasion, reasoning, corporal punishment, cajoling, bribery and exhortations by the minister and by the leader of the Y M C A had been resorted to in turn but with no results. According to the mother, the boy was a kind, friendly, easy-going lad well liked by his companions. He liked to read and enjoyed watching athletic games but never took any active part in them. In fact he refused to do any work that required physical exertion. He always wanted to do his work sitting down. The mother also stated that the boy had a huge appetite and was extremely fond of sweets that he appeared tired and listless and that it was difficult to arouse him in the morning.

Examination revealed that he was a tall fat boy with a female type of skeletal development. His skeletal development in conjunction with the excessive amount of fat which was deposited chiefly over the breasts, hips and abdomen gave him a typically feminine appearance which was heightened by the fact that the skin of the face was smooth, fair and highly colored and by the further fact that the voice was still high pitched. The genital organs were normal but there was no

evidence of any secondary sex characteristics. All the clinical and laboratory tests confirmed the diagnosis of the adolescent form of Froelich's dystrophy.

On questioning, the boy admitted that he had been stealing. Furthermore, he stated that he had a tremendous craving for sweets, especially ice cream, and that he was unable to curb it. In fact he told us with tears in his eyes that the only thing worth while in life was ice cream and that he had to have it. It was pathetic to see a big, fat, handsome looking boy crying over the statement that he loved ice cream more than anything in life and that he had to have it. He claimed that the craving was overwhelming and overpowering and that his sole purpose in stealing money was to have the wherewithal to buy large quantities of candy and ice cream.

In this case it was felt that there was a direct causal relationship between the stealing and the glandular disturbance. This belief was based on the fact that as a result of the deficiency in the hormonal secretion of the pituitary gland the sugar tolerance had increased way above normal. A normal person can eat a certain amount of sugar, but if he eats more than that amount glycosuria will develop—the excess sugar will be spilled over and excreted by the body and a form of diabetes will develop. But this boy could eat huge quantities of sugar without showing any signs of diabetes or glycosuria. The pituitary deficiency was responsible for his huge appetite and especially for his craving for sweets. This craving was innate and elemental and beyond the power of the patient to control. He was driven by an uncontrollable urge to eat more and more sweets. The parents, because of their lack of understanding, were not willing to supply him with unlimited amounts of candy, nor were they able to do so. As a result, the boy resorted to direct, aggressive measures in order to obtain the things he blindly craved. These direct aggressive measures unfortunately were highly antisocial and brought him into conflict with the law.

It thus becomes apparent why all previous methods of discipline had failed. They were all doomed to failure because perforce neither exhortation, bribery nor corporal punishment could ever correct a pathologic condition based on organic changes.

The boy, instead of being scolded, whipped, bribed or threatened with incarceration in a reformatory, was given glandular therapy. As a result his sugar tolerance was lowered to the normal level. This in turn caused him to lose his intense craving for candy and ice cream. There being no further need for money, the stealing stopped automatically.

CONCLUSION

I wish to add one thought. In the past decade the discoveries in the field of endocrinology have been kaleidoscopic in their rapidity and startling in their magnitude. Yet endocrinology is far from being a closed book. All over the world physiologists, biochemists and clinicians are carrying on a tremendous amount of research. One can therefore confidently expect the announcement of many more discoveries that will aid in the study and treatment of behavior disorders and personality changes in children.

Doctors' Building, Garfield Place

First American Hospital for the Insane—The first American hospital exclusively for the insane had its beginnings in November 1766, when the governor of Virginia Colony, Francis Fauquier, made an earnest appeal for such a hospital in an address to the House of Burgesses. The hospital was opened for the reception of its first patients Oct. 12, 1773. John de Sequeira, a leading doctor of Virginia, served as the first visiting physician, retaining his post until 1795. James Galt was appointed the first keeper. The functions of keeper and physician remained distinct until the year 1841, when they were combined in the person of Dr. John M. Galt, the first superintendent—Deutsch, Albert. *The Mentally Ill in America*. New York, Doubleday, Doran & Co., Inc. 1937, p. 69.

THE MANAGEMENT OF THE SEPTIC PATIENT WITH OTITIS MEDIA

J. H. MAXWELL, M.D.

Assistant Professor of Otolaryngology, University of Michigan Medical School

ANN ARBOR, MICH.

The medical and surgical management of the septic patient with suppurative otitis media presents a distinctly individualized problem, one which does not submit to the simple solution of adapting the patient to one standardized procedure. I use the expression "the septic patient with otitis media" rather than "the patient with otitic sepsis" in order to emphasize the frequently forgotten fact that the otitis media may be an incident in the course of an infection elsewhere in the body responsible for the patient's sepsis.

The term "sepsis" is used rather broadly to represent a clinical picture manifesting numerous variations. It cannot have the concreteness indicated by such terms as bacteremia and septicopyemia. In the present discussion those patients have been considered septic in whom, during the course of an otitis media, leukocytosis has developed with intermittent fever rising to 103 F or higher at least once daily and who have continued to manifest such evidence of illness without abatement for five days or longer. Those patients who have experienced gradually subsiding fever and leukocytosis following myringotomy are not included.

For the sake of generalization it may be said that a septic patient with otitis media may fall into one of three rather clearly defined groups.

In the first group there is an infectious process, local or general, producing the clinical picture of sepsis antedating the otitis media. This situation assumes great importance when the otologist sees the patient for the first time after the otitis media has become established. Unless a careful and detailed history is obtained he may be led to performing a mastoidectomy or ablation of a sigmoid sinus when the source of the sepsis is extra-aural. This is particularly true in those cases of tonsillitis and suppurative sinusitis producing the picture of sepsis or even an actual septicopyemia in which an otitis media develops secondarily and contributes but little to the septic course. If the aural infection is severe, one may have to summon considerable courage to refrain from an operation which, owing to its prematurity, might have disastrous results.

The second group of cases is that in which there develops during the course of an acute suppurative otitis media an intercurrent infection which in itself is responsible for the appearance of sepsis. Because of this possibility, one never should be hasty in performing a mastoidectomy on a septic patient without careful attention to a complete physical examination. Most otolaryngologists have had the experience of having referred to them for immediate mastoidectomy an acutely ill and septic patient only to find developing during twenty-four hours of observation the signs of another infectious process. Most common among the intercurrent infections are pneumonia and puerperal erysipelas, rheumatic fever, endocarditis, coccidial pneumonia, or one of the acute exanthems may on occasion be found. Pneumonia, especially, may confuse the otologist when it appears during the course of a severe aural infection. The sudden rise in temperature and leukocyte count suggests the possibility of invasion of the sigmoid sinus; preeminently is this the case in children in whom physical signs in the chest may be very obscure. At

untimely mastoidectomy during the development of bronchopneumonia might well prove fatal

The third group of cases represents those of real otitic sepsis in which the infection in the middle ear and mastoid is responsible for the whole picture. These cases require truly individualized management, both medical and surgical. In such a patient one may be dealing with a toxemia or with a true septicopyemia, which may or may not be related to actual phlebitis or thrombosis of the sigmoid sinus. Although no hard and fast rules can be drawn, there are a few sound principles to follow which have proved helpful.

1 In the first place it must be remembered that, since cases of otitic sepsis are rarely surgical emergencies, sufficient time can be taken to determine definitely that the sepsis is of otitic origin. In many cases of otitic sepsis there may be reasonable doubt that the condition of the ear is entirely responsible for the patient's illness. Such doubts frequently exist with regard to patients in whom the otitis media seems to be resolving, as evidenced by discharge which has decreased in amount and has become more mucoid. Such a patient may have temporoparietal or trigeminal pain with nocturnal exacerbation, or there may be a point of tenderness over the temporal root of the zygoma, the mastoid tip or the post-sigmoid cells, or there may be radiographic evidence of osseous destruction in one of the peripheral parts of the temporal bone. These observations, which suggest a secondary active focus in some portion of the mastoid during the resolution of the otitis media, are of material importance in the study of the patient. In the presence of an otitis media of four or five days' duration, especially if complicating an acute exanthem which in itself might well be responsible for the sepsis, one may hesitate in condemning the middle ear and mastoid as being responsible for the alarming manifestations. Doubts may be held also in those patients who present evidence of an acute exacerbation of a chronic otitis media. The lack of mastoid tenderness due to the presence of a thick eburnated mastoid cortex, inconclusive radiographic examinations and the lack of aural symptoms make it difficult to condemn the ear as the chief factor in the production of sepsis. In these difficult cases the time taken to make a diagnosis must be utilized well. The following procedures have been helpful on many occasions in making a decision regarding the importance of an infection of the ear in a septic patient.

(a) Bacteriologic studies of the aural discharge

(b) A record of the temperature, pulse and respiration every two hours

(c) Daily examinations of the blood at the same hour. These should include a red and white cell count, the hemoglobin determination and a differential count with Wright's stain. Increasing leukocytosis, progressive secondary anemia and an increase in the number of immature polymorphonuclear leukocytes are significant.

(d) Daily examinations of the urine, including study of the stained sediment from a centrifuged specimen. One must remember that streptococci may be found in the urine before their presence is determined by blood cultures.

(e) Daily blood cultures. These should be taken at the peak of a temperature rise or right after a chill. Here one must realize that one negative blood culture means little. Also it is important to remember that

pneumonia, severe tonsillitis and other acute infections may produce positive blood cultures.

(f) Examination of the patient twice a day with special reference to the heart (endocarditis), the lungs (pneumonia), the kidneys (coccic kidney), the skin (acute exanthem), the eye grounds (evidence of increased intracranial pressure), the central nervous system (evidence of meningitis, brain abscess, petrositis or sinus thrombosis) and the cervical glands (suggestive evidence of jugular phlebitis).

(g) X-ray examinations of the chest repeated every forty-eight hours or even every twenty-four hours if there is a reasonable doubt that the ear is responsible for the sepsis and if the other conditions under consideration have been eliminated as possible etiologic factors. In the early stages of acute pneumonitis, both physical signs and radiographic evidence may be lacking but may make their appearance after twenty-four or forty-eight hours. The X-ray examinations may become positive some time before rales or signs of consolidation can be determined from the physical examination.

(h) Radiographic studies of the mastoids. In cases of sepsis it is important to know what type of structure is present within the temporal bone even though the infection is of only two or three days' duration. If the roentgenogram reveals a diploic structure, the ear is a more likely source of the sepsis than if the mastoid were sclerotic or of the large cell pneumatic type.

Thus a conscientious effort is made either to discover some occult extra-aural infection or to determine definitely that the sepsis is of otitic origin.

There are times when the otologist must stand alone against the pediatrician who hears no rales in the chest, the radiologist who finds the chest clear and the mastoid hazy, and the anxious parents who demand therapeutic action. However, he should insist on time for observation of the patient before performing the mastoidectomy if it is not perfectly clear to him that the ear is responsible. Conversely, the otologist may encounter opposition in demanding that an immediate operation be performed on a septic patient who has an otitis media of five or six days' duration and whose roentgenograms demonstrate a diploic mastoid with little or no evidence of pathologic alteration.

2 It must be remembered that the presence of organisms in the blood stream does not necessarily indicate an actual thrombus in the sigmoid sinus. The organisms may enter the general circulation from either the middle ear or the mastoid directly into the jugular bulb or the sigmoid sinus or by way of the countless small veins throughout the temporal bone. The possibility of a septic thrombus in the lateral sinus must be borne in mind, however, at the time of operation.

3 The surgical field should be completely covered.

(a) Careful exenteration of all accessible pneumatic bone is necessary. Special attention must be given to the postsigmoid cells and to the cells deep in the floor of the mastoid mesial to the facial nerve. On several occasions what appeared to be solid healthy bone has been found in the floor of the mastoid concealing a small parasinus abscess at a deeper level near the jugular bulb.

(b) The sigmoid sinus should be exposed widely in every septic case. This exposure should extend from the knee to a position deep in the floor. If an actual thrombus is not present this exposure eradicates numerous small emissary veins which may be transmitting organisms into the general circulation. Even though the sigmoid plate may appear to be intact,

smooth and ivory-like, there may be a concealed paraspinal abscess beneath it. Experience has shown that such a collection of pus beneath an intact sigmoid plate usually means a septic thrombus within the sinus, this is true even when the duration of the infection has been but five or six days.

(c) If there is reasonable doubt about the patency of the sigmoid sinus, it should be explored through an incision. Needle puncture is not adequate. In several instances I have found a septic thrombus in the sigmoid sinus when the sigmoid plate appeared to be normal and when the parietal wall of the sinus demonstrated only a slight gray discoloration to suggest a pathologic change.

(d) If the sinus appears to be normal at the time of operation, and if sepsis continues unabated for five or six days after operation, and especially if metastatic abscesses appear, one should operate again and ablate the sigmoid. The decision regarding interference with the jugular vein must depend on the pathologic changes found in the sigmoid sinus. Before such an attack is made on the sigmoid sinus other possible causes for the continued sepsis must again be excluded.

(e) The contralateral ear must be a closed issue before the secondary attack on the sigmoid sinus. Even if the objective examination and radiographic studies tend to suggest satisfactory progress in what has appeared to be a less severe suppurative process in the opposite ear, it is often advisable to perform a complete mastoidectomy on this second ear before attacking the sigmoid sinus on the original side. If the infectious process in the second mastoid is found to be more extensive than anticipated, further delay may be considered. If this second mastoid presents no gross evidence of an unusually severe infection, one should proceed immediately with the attack on the sigmoid sinus of the original side, as already mentioned.

4. Whether or not an actual invasion of the sigmoid sinus or jugular bulb is found, meticulous attention must be given to the postoperative medical management. Even though the surgical attack has been adequate in removing the active focus, most patients will continue to show evidence of sepsis for several days, during which all available supportive measures must be used.

The progress of the septic process can be followed if the following procedures are executed:

(a) Recording of the temperature, pulse and respiration regularly at intervals of two hours.

(b) Daily examination of the blood to note the presence of leukocytosis, anemia and immature polymorphonuclear leukocytes.

(c) Daily blood cultures.

(d) Daily examinations of the urine to note evidence of kidney damage.

The postoperative regimen should include:

(a) Forced fluids to 4 or 5 liters a day for adults. If the patient is unable to take adequate fluids by mouth he should be given a continuous intravenous injection of 5 per cent dextrose. If he is vomiting he must be given physiologic solution of sodium chloride in addition, the amount of saline solution given intravenously should approximate roughly the amount of fluid lost by emesis. This amount replaces the dissipated body chlorides to a certain extent.

(b) High caloric-high vitamin liquid diet.

(c) Reduced iron in doses of 0.5 Gm three times a day.

(d) Repeated small transfusions of whole blood from different donors. Generally speaking, it is well to give

the adult patient about 200 cc of blood every second or third day during the period of continued sepsis.

(e) In cases of hemolytic streptococcic septicemia, sulfanilamide seems to be beneficial. This should be given by mouth when possible, or by vein as a 0.5 per cent solution in 5 per cent dextrose. If given at all it should be used in adequate dosage depending on the weight of the patient. The success of sulfanilamide therapy depends on its intelligent administration. Large doses should be given at first to bring the sulfanilamide content of the blood up to about 10 mg per hundred cubic centimeters and should be followed by smaller doses to maintain the blood at that level. This of course demands frequent determinations of the sulfanilamide of the blood. Although results are not conclusive at this time, there is very definite evidence to suggest that this drug is of real value in treating the septic patient.

SACRO-ILIAC TUBERCULOSIS

FRED THOMPSON, MD

Fellow of the New York Orthopaedic Dispensary and Hospital
NEW YORK

In the records of the New York Orthopaedic Dispensary and Hospital there are the histories of twenty-three cases of sacro-iliac tuberculosis treated by operative fusion. Until 1919 the therapy employed was conservative, with rest in bed, heliotherapy and supportive measures. After 1920 arthrodesis of the sacro-iliac joint was always the method of choice unless the condition of the patient was such that operation would be immediately dangerous. This study is limited to those cases in which treatment was by operation.

Of the twenty-three patients, thirteen were female and ten were males. The average age at onset was twenty-three years, with four patients younger than 15. The right side only was affected in 52 per cent (twelve patients). Both sides were affected in two patients.

MULTIPLE LESIONS

It is felt that sacro-iliac tuberculosis is one of the rare forms of tuberculosis and usually indicates a wide spread infection in the body. Seventy per cent of the patients (sixteen) showed evidence of tuberculosis in other parts of the body, and the infection in all but two of these was felt to be active at the time the sacro-iliac joint was fused. Forty-three per cent (ten patients) had pulmonary tuberculosis, and in nine the infection was active at the time of operation. Thirty-five per cent (eight patients) had lesions in the vertebral bodies as well as in the sacro-iliac joint and in three the infection was active. Several showed additional tuberculosis in the shoulder, wrist, elbow, ankle, hip or sternum. It is probable that more extensive examination of the urine and the tonsils would have placed the incidence of multiple foci at an even higher percentage.

SYMPTOMS AND SIGNS

The average duration of symptoms before operation was two and one-half years, the longest fourteen years and the shortest three weeks. All of the patients had pain. Most commonly it was a dull ache in the buttock, frequently described as "a pain in the hip." This was present to a greater extent on standing and walking than lying. Unless additional disease was present in neighboring joints, the pain was limited to the buttock.

or the posterior aspect of the hip region, or followed the distribution of the pain in sciatica. Pain low in the back was present, together with pain in the buttock, only when there was active tuberculosis at the lumbosacral joint (three patients). Pain radiating down the anterior aspect of the thigh from the hip to the knee was present in one case, together with pain in the buttock, as a result of active tuberculosis of the hip.

Only seven patients (30 per cent) had sciatica. It was always on the side of the affected joint. An interesting feature of this sciatica was that five of the seven patients had a large abscess in the buttock, causing tension or inflammation of the ligaments, fascia and gluteal muscles. In two cases aspiration of the abscess was performed and resulted in immediate disappearance of the sciatica.

Two patients had sciatic pain without an abscess in the buttock. One was relieved only after lumbosacral fusion for active tuberculosis, the sacro-iliac fusion having failed to relieve the sciatica. The other was completely relieved by sacro-iliac fusion within the first few postoperative days. Fusion of the joint could not have taken place in that short span of time. From these facts it would seem that disease of the sacro-iliac joint in itself does not tend to produce pain of the sciatic type.

Aside from pain, a few patients complained of listing of the trunk, limping and atrophy of the thigh, but these signs were not prominent features in the series. Physical examination showed that the various so-called signs of sacro-iliac disease were absent as frequently as they were present. Compression of the wings of the ilia, in an attempt to move the sacro-iliac joints and straight-leg raising, produced pain in only half of the cases.

DIAGNOSIS

The preoperative diagnosis was not easy. Clinical signs and symptoms suggested disease of the joint but were in no way pathognomonic of tuberculosis. Roentgenograms and laboratory tests also offered no conclusive evidence. All these factors, however, indicated the need of exploration of the joint for possible tuberculosis. The white blood count was usually within normal limits, with a slight elevation of the lymphocyte count. The sedimentation rate was elevated. The Mantoux test was always positive. In the diagnosis of tuberculosis of this joint, as of other joints, the negative Mantoux test proved to be of the greatest value in ruling out disease.

Roentgenograms showed active destruction of the joint surfaces, usually near the antero-inferior margin of the joint. Soft tissue shadows offered but little guidance, owing to the depth of the tissue that had to be penetrated by the rays. Oblique views showing the opposing surfaces as parallel planes were sometimes necessary. They were also of great value in determining the degree of fusion that had resulted from the operation.

An attempt was made to prove the presence of tuberculosis at operation by examination of the pus or tissue section or by inoculation of guinea pigs. Tests with guinea pigs and examination of tissue were not always done together during the earlier years of the series. There were twenty-one cases of proved tuberculosis. The other two cases are included either because the patient had tuberculosis elsewhere in the body or because the results of tissue examination were strongly suggestive and the subsequent course, as shown by clinical and roentgenographic examination,

was typical of the disease. Three cases in which the joints were explored and fused for tuberculosis were not included in the series. The condition proved to be suppurative osteomyelitis on subsequent tissue examination, and the postoperative course was typical of that disease.

OPERATION

Arthrodesis of the joint was usually accomplished by a posterior approach with the patient under ethylene anesthesia. The incision was curved along the iliac crest and posterior superior spine toward the posterior inferior spine. The origin of the gluteus maximus was stripped up and the posterior ligaments reflected off the bone. A view of the joint was obtained by chiseling off the posterior superior spine and a portion of the posterior border of the body of the ilium. The joint was easily entered at the caudal end of the incision near the posterior inferior iliac spine. The joint cartilage was removed with the chisel and curet. All the diseased bone that could be removed easily was curetted out. No attempt was made to obtain all the cartilage or carious bone from the joint, since arthrodesis and healing were accomplished in all but one case even though surgical invasion of the joint was minimal. No attempt was made either to curet out the diseased area at the antero-inferior end of the joint, where the disease is nearly always seen by roentgenograms to be more extensive. The neighboring sides of the sacrum and the ilium were chipped up, forming small and large, free and attached bone chips. These were brought into contact. Additional bone, if needed, was taken from the external surface of the ilium. Closure was accomplished by replacing the origin of the gluteus maximus and approximating the skin.

After the operation the patient was left in bed with a spine brace in some instances and with no support at all in others. A plaster cast was unnecessary and was dispensed with as too cumbersome and uncomfortable.

When abscesses were observed at operation they were usually aspirated before the surgical procedure was begun. This was principally for convenience, so that the operative field would not be soiled. In a few instances the walls of the abscess were excised or treated with phenol. Generally they were ignored. Sinuses were avoided if they lay on the outskirts of the possible line of incision. If directly in the field of operation they were excised. Closure of the wound was made tight in an attempt to obtain primary union. Such union was secured in only one of four patients who had a sinus before operation but was obtained in ten of the nineteen patients (41 per cent) in whom no sinus had been present before operation.

A singular lack of motion was noted at the joint even when the so-called sacro-iliac signs had been present before operation. It is felt that the degree of motion that takes place is comparable to that associated with fibrous ankylosis of the joint. The difference between fibrous ankylosis and fusion of the joint is the factor that will decide the outcome of the destructive disease. Fibrous ankylosis is not always sufficient to allow the body to master the tuberculosis, bony ankylosis is.

SINUSES

The postoperative sinuses were treated as uninspiringly here as in other parts of the body. One simply waited for the disease in the bone to become quiescent, knowing that in time the sinus would close. Secondary infection was avoided as carefully as possible. Exuberant

ant granulation tissue was cut off with scissors or burnt away with silver nitrate

In twelve cases (52 per cent) draining sinuses developed after the operation. Most of them closed spontaneously within five months, usually when the disease began to show abatement by roentgenograms. Two sinuses drained for over five years but have since healed completely, and the patients are at active heavy work. It was not felt that the advent of a sinus postoperatively was an occurrence to be feared. The sinus usually closed when the disease in the bone subsided. Except in the patients who died, all the sinuses in this series eventually healed.

END RESULTS

The length of the follow-up period varied from six months to ten years. The average was 4.9 years.

Eighteen patients (78 per cent) are believed to be healed of their sacro-iliac tuberculosis, seventeen (74 per cent) have been actually cured and restored to active work and usefulness, several for as long as eight or ten years. One patient with tuberculosis of both hips is still under treatment, although it is three years since solid fusion of the sacro-iliac joint occurred and she is free from her sacro-iliac pain. The length of stay in bed after operation varied, depending on whether tuberculosis was active elsewhere in the body (group 1) or whether the focus was quiescent (group 2).

Sixteen patients in group 1 showing either active pulmonary lesions or elevation in temperature, pulse rate or sedimentation rate, were kept in bed until, clinically, the activity had abated. This required sometimes as long as three years. Every effort was made, however, to get the patient back to work as soon as possible, provided no other active focus was present. Although roentgenograms were a great aid in determining the degree of subsidence of the lesion in the bone, clinical observations on the pulse, temperature, weight and especially the sedimentation rate were a more correct gauge of the disease activity elsewhere in the body.

The average length of stay in bed after operation for the seven patients in group 2, who did not have an active demonstrable focus elsewhere in the body, was three months. When the temperature, pulse and sedimentation rate remained normal for several weeks the patients were allowed to get up. Patients in this group went home in four months.

Although "up in three months and home in four" seems at first glance somewhat radical for patients with tuberculosis, this is not quite the case with tuberculosis of the sacro-iliac joint. The mechanism of the joint is such that, were it not diseased, arthrodesis could be done and the patient be up and walking as soon as the sutures were removed. When active tuberculosis is present at operation absorption of previously diseased bone may continue for a few months. As the joint becomes immobile, the lesion is walled off and condensation of the bone occurs. The joint is solid long before condensation takes place, probably at six weeks. It is not necessary to insist on rest in bed until, as shown by roentgenograms, the diseased area is homogeneous bone. Walking and even the commencement of work did not in a single case in this series cause a recession in healing of the bone at the area of the disease. The only criteria, then, for allowing the patient to be up are the activity of other foci in the body. The fusion of one actively tuberculous joint serves as a lessening of the load the system must bear in its battle with the disease elsewhere. With the subsidence

of the joint disease after fusion, the clinical expressions of activity, such as elevation of temperature and sedimentation rate, rapidly disappear, even when known foci of tuberculosis are existent in other areas of the body. That the sacro-iliac fusion results in cure of the local tuberculosis is shown by the fact that, when once the joint is solid and the bone has attained a healthy appearance in roentgenograms, a recurrence has never been noted. This is true even when other foci flare up with lowered resistance of the body.

DEATHS

Five patients (21 per cent) died, all within one year after operation. Two died of pulmonary tuberculosis, one of miliary tuberculosis, one of cardiac decompensation due to rheumatic heart disease and one of tuberculous meningitis. None died as the immediate result of operation.

The question is naturally raised whether or not operative intervention was the contributing cause of these deaths. The patient who died of rheumatic heart disease had a decompensating heart and was referred here by her medical attendant for operation. At the time of her death, one year later, there was nothing to indicate that she had another focus of tuberculosis. Meningitis developed in another patient, suddenly, during the twelfth postoperative month, while he was convalescing at rest in bed. Death occurred eleven days later. The patient who died of miliary tuberculosis had been referred for surgical intervention from the tuberculosis ward of another hospital. She had recently recovered from pleurisy, her lung fields were pronounced normal and it was stated that her general condition did not contraindicate operation. Two weeks after operation roentgenograms of her chest showed miliary tuberculosis. She died six months later. The two patients who died of pulmonary tuberculosis showed active lesions in the chest before operation. Afterward roentgenograms and auscultation of the chest did not elicit signs of increased activity until the third postoperative month. Both patients died six months after operation in other hospitals.

This review suggests that these last three deaths may have been caused by operation, yet in nine of the ten cases with additional pulmonary tuberculosis eight showed no ill effects from the surgical procedure, although nine were considered active at the time of operation.

COMMENT

Petter,¹ in writing on the conservative treatment of unproved sacro-iliac tuberculosis, reported an average length of stay in bed of 891 days. In the present series of cases the average was 240 days. Petter found a mortality of five in thirty-one cases, compared with a mortality of five in twenty-three cases in the present series.

Smith-Petersen² reported thirteen cases, with four deaths. He found sciatica present in 77 per cent, as compared with 30 per cent in the present series.

CONCLUSIONS

1. Tuberculosis of the sacro-iliac joint and ligaments does not usually produce sciatic pain unless in relation with its resulting tension, is an accompanying feature.
2. Fusion of the sacro-iliac joint results in cure of the local tuberculosis.

SULFANILAMIDE IN THE TREATMENT
OF GONORRHEAL VULVOVAGINITIS

SAMUEL J. HOFFMAN, MD

MAURICE SCHNEIDER, MD

MAURICE L. BLATT, MD

AND

RUSSELL D. HERROLD, MD

CHICAGO

Gonorrheal vulvovaginitis in children is a common disease, at the Cook County Hospital alone we treat about 150 patients a year. Brunet and his co-workers¹ estimate that it occurs in from 1 to 5 per cent of the female children of the poor sections of the larger cities. We feel that this estimate is very conservative. In 1930 we were called to an institution to take care of several patients with vaginitis. After taking smears of all the girls, approximately 300, we found that 20 per cent were positive for gonococci. In Chicago there is a high percentage of active cases among the Negro population.

The sources of infection are numerous. In institutions the diaper appears to be the chief source of infection. Towels, linen, thermometers, bath tubs, attendants and nurses also may convey the organism from one child to another. About 80 per cent of our patients are traced directly to their homes, where bed linen, bath tubs, circular toilet seats and towels are chief sources of infection. About 10 per cent of the cases are due to rape.

The susceptibility of a child to gonorrhea is very great. Instead of the resistant squamous epithelium found in adults, there is present a pseudosquamous or delicate columnar epithelium. Vaginal secretions containing lactic acid are gonococcidal in the adult but are absent in the child. In addition the small size of the labia and the absence of pubic hairs decrease the protection against the entrance of gonococci.

Most young children present no symptoms other than the discharge on the diaper. In older children itching, burning and frequency of urination are noted. An occasional rise in temperature, even in the absence of complications, has been found.

Stein, Leventhal and Sered² found an involvement of the cervix in most cases of acute gonorrhea. We have found the inflammation a general one. The hymen, vulva, vagina, urethra and cervix are all involved in the acute stage. The labia are often swollen and hyperemic and granulations which bleed easily when touched with an applicator are often seen in the vagina. We have found the cervix involved in practically all acute infections since making routine vaginoscopic examinations. The cervix is swollen and hyperemic. Sometimes ectropion is present.

In the chronic stage the vagina is bluish red and sometimes succulent. The cervix may be diffusely involved, but in many patients only small punctate hemorrhagic areas are noted.

While some authors maintain that gonococci are found only in the acute stage and consider all vaginal discharges as of gonorrheal etiology, we have admitted and treated only those patients in whom gonococci were found.

Before the use of sulfanilamide, the treatment of gonorrheal vulvovaginitis consisted mainly of chemicals applied locally and the use of biologic agents. Since 1928 we have used various chemicals locally, such as silver nitrate, mercuriochrome, acriflavine, potassium permanganate, merthiolate, metaphen ammoniated mercury and lactic acid. Of all these local applications, we have obtained the least discouraging results with the silver nitrate in 0.5 to 1 per cent strength in 10 per cent gelatin. With this treatment we obtained negative smears in some instances in from six to eight weeks, which result was considered very satisfactory at that time. Most infections remained positive for more than five months. In a series of 124 patients that we treated at the Cook County Hospital the average length of stay in the institution was 4.6 months. Recurrences were very common. Forty of the patients returned because of recurrent infection in from two weeks to eight months after discharge from the hospital. Undoubtedly many more had relapses but did not return.

A temporary wave of enthusiasm followed the introduction of biologic products in the treatment of gonorrheal vulvovaginitis. In 1930 we³ reported a large series of cases treated with immune horse serum, gonotoxin broth filtrates injected intracutaneously and subcutaneously, ectoantigen intracutaneously, whole gonococci intracutaneously, and local application with gonotoxin. In 1934 we⁴ reported on lysed gonococci in the treatment of gonorrheal cervicovaginitis. In general the results were not particularly encouraging with any of these methods of treatment.

In 1933 Lewis⁵ reported on the use of estrogenic substance, which changes the immature vaginal epithelium to the mature thick epidermis-like structure of the adult, and containing lactic acid secretion which supposedly is gonococcidal. We treated eighteen patients with theelin, giving 2,000 international units three times weekly. The amounts used in individual patients varied from 64,000 to 184,000 units. In general the results were somewhat better than with the silver nitrate treatment, but still not very encouraging, since 40 per cent of the patients had recurrences.

Working independently, and at about the same time, Reuter⁶, Dees and Colston,⁷ and Herrold⁸ reported favorable preliminary observations on the use of sulfanilamide in adult male patients with gonorrhea. Since overenthusiasm might cause the pendulum to swing too far in favor of such a drug, we have tried to guard ourselves with a cautious skepticism in the application of sulfanilamide to gonorrheal vulvovaginitis. The history and pharmacology of sulfanilamide have been discussed amply in many previous publications. One of us (Herrold) has found that sulfanilamide in concentrations stronger than 1:10,000 is bactericidal in vitro, although such determinations must be made in periods of hours to demonstrate gonococcidal action instead of the standard twenty minute contact as used with other antiseptics. The exact mechanism of its action is not known. However, the primary factor is that of bacteriostasis with eventual bactericidal effects.

Carey⁹ of Boston treated two cases of gonorrheal vulvovaginitis in children with sulfanilamide and obtained prompt favorable results in both cases.

Our series includes a group of twenty-five children varying in age from 3 months to 10 years. Three of this group had chronic infections at the time of institution of treatment, one subacute and the remainder acute infections. No local treatment was used and sulfanilamide was administered orally in fruit juice to all the patients. The supply of sulfanilamide for this study was furnished by the Winthrop Chemical Company. A standard dosage was used throughout.

TABLE 1—Dosage of Sulfanilamide

| Days | Dosage per Day |
|---------------------------|--|
| 1st and 2d day | $\frac{3}{4}$ grain per pound |
| 3d to 7th day inclusive | $\frac{3}{8}$ of original dose or $\frac{9}{16}$ grain per pound |
| 8th to 21st day inclusive | $\frac{1}{2}$ of original dose or $\frac{3}{8}$ grain per pound |

During the first two days the daily dosage was three-fourths grain (0.05 Gm.) per pound of body weight in four equally divided doses at intervals of six hours. During the next five days the dosage was reduced to three-fourths of this amount, or nine-sixteenths grain (0.04 Gm.) per pound daily. During the second and third weeks the dosage was reduced to three-eighths grain (0.024 Gm.) per pound daily or one-half the initial dosage. At the end of a three weeks course of treatment a rest period of one week was given regardless of the results of smear examinations. All patients whose smears were positive at the end of this rest period were given a second course exactly like the first. A rest period was also given at the end of the second course of treatment, and for the majority of patients who were still infected at the end of the second rest period a third course of treatment was prescribed. A few patients were given a fourth course of treatment after the third rest period. An outline of the dosage is given in table 1.

Results in this group of twenty-five patients are summarized in table 2. It may be noted that only seven patients were apparently cured during the first course of treatment, or under a period of twenty-one days. By apparent cure we mean a clinical disappearance of all signs of infection from the urethra, vagina cervix and rectum, as well as negative smears from these areas. None of this group of seven were cured under a period of sixteen days, and the average was 17.3 days. Four of the group cured during the first course of treatment had acute infections, two chronic and one subacute. During the second course of treatment, nine additional patients were cured between the thirty-fifth and forty-ninth day of treatment, with an average of 42.9 days. Seven of the nine patients not cured were given a third course of treatment, and one of this group was cured during the third course or in sixty-three days. Four of the six remaining patients not yet cured were given another course of treatment after the usual rest period, and only one of this group of four was cured by such additional treatment. Analysis, therefore, reveals that approximately two thirds of the patients were cured by one or two courses of treatment, after which there was a very marked drop in the percentage of benefit derived by a third and fourth course of treatment. It would seem then that patients who do not respond to two standard courses of treatment have

gonococcic infections that are relatively resistant to therapy with sulfanilamide.

It is well known that many patients with gonococcal vaginitis, who are thought to be cured by the standard methods of examination, will have recurrence after a variable period. All patients in this group were kept in the hospital for two weeks after negative smears were obtained and all those listed as cured had follow up examinations from one to three months after discharge from the hospital.¹⁰ The examinations revealed that they were symptomatically normal, and smears were negative for gonococci. One patient who was examined after discharge from the hospital was found to have had extracellular diplococci but no discharge in the vagina and she is not included in the group of eighteen of this series who are listed as cured.

Negative smears will be found in many patients during the treatment or for a period of from three to seven days after the discontinuance of sulfanilamide. On the other hand, it was exceptional for patients to have a recurrence if they were clinically and microscopically normal for a period of two weeks after discontinuance of the drug. Smears were taken in a routine manner through the vaginoscope and sent to two laboratories for examination.

All reports on the use of sulfanilamide in any substantial series of patients have included a varying sort of side reactions from mild to so severe that discontinuance of the drug seemed advisable. However, in our group of children the incidence of side reactions was strikingly less than in any comparable series of adults that have been reported. Gastrointestinal symptoms, which so commonly occur in adult patients, were entirely absent in this group of children. Only one patient had a typical "drug fever" reaction, which occurred on the tenth day and was associated with urticaria and swelling of the face. Two other patients had a slight fever of less than 100 F. One patient had a rather severe epistaxis, and three others mild epistaxis. A definite anemia occurred in only one patient. Clinically, the patient had no subjective symptoms, but unfortunately this was one of the patients whom we

TABLE 2—Patients with Gonococcal Vaginitis Treated with Sulfanilamide

| Course | Number of Patients | Number of Patients Cured | Average Number of Days to Cure |
|--------|--------------------|--------------------------|--------------------------------|
| First | 23 | 7 | 17.3 |
| Second | 18 | 9 | 42.9 |
| Third | 7 | 1 | 63.0 |
| Fourth | 4 | 1 | 60.0 |

were unable to observe after discharge from the hospital, so that we are unable to state the ultimate condition of the anemia. It is noteworthy that the majority of this group of patients had a definite anemia on entrance to the hospital, and they were given as a routine liver and iron therapy for this condition. Such treatment was continued during the administration of sulfanilamide, and generally there was a definite improvement in the blood on the combined treatment similar to the response to liver and iron therapy without sulfanilamide. The patient who had sulfanilamide fever and urticaria also had albuminuria, which cleared up promptly following the discontinuance of the drug. Cyanosis was not noted in any of this group on the dosage outlined.

10. Since this paper was submitted all cases have been rechecked from four to seven months after discharge from the hospital and have been found to be negative again microscopically at this time.

COMMENT

While we appreciate that a larger percentage of patients might have been cured during the first course of treatment by a greater dosage of sulfanilamide, we wished to keep the amount of the drug administered within the limits of safety for ambulatory patients. In general, a large percentage of the patients with gonococcal vaginitis must be treated without hospitalization. Hageman¹¹ reported in a series of sixty-eight children, a much greater incidence of complications than we observed in our series. Three of his series had gonococcal vaginitis and the others miscellaneous infections. He mentions that cyanosis associated with methemoglobinemia was encountered in approximately 50 per cent of the cases treated. He also states that one in every six patients treated had fever between the seventh and tenth day after the institution of sulfanilamide therapy and that one half of the patients with a febrile complication had an accompanying morbilliform rash. He states in regard to dosage that, in general, 1 gram daily to 20 pounds (9 Kg.) of body weight was given in divided dosage at intervals of six hours. This is the same dose that we used for the first two days of treatment but, while Hageman does not state the duration of this dosage, it is assumed that it was continued during the duration of treatment, which could no doubt account for the high incidence of reactions as compared to our series with a schedule of decreasing doses.

It is well known that patients with gonococcal vaginitis may be clinically free from symptoms for months and then have an exacerbation with positive smears. We have noticed this during the past ten years following other forms of treatment but, as a rule, there would be a substantial number with recurrence during a period of from one to three months following discontinuance of treatment. In this series after the use of sulfanilamide, there was but one patient of those considered cured when they left the hospital who later showed a positive smear but no clinical symptoms. All patients listed as cured had follow-up examinations after leaving the hospital, but most of them had two such examinations. Therefore, we feel that with an apparent cure two weeks after discontinuance of sulfanilamide there is less likelihood of a later recurrence than after the former methods of treatment, including endocrine therapy.

It is not known why certain patients, on a like dosage, do not respond favorably to the administration of sulfanilamide. It seems noteworthy that in our series there were two girls from the same family, one of whom was cured in twenty-one days, while her sister failed to be cured after three courses of sulfanilamide. It is likely that these two children had the same type of gonococci, so that in this instance at least, primary serologic types were not an explanation of the difference in the clinical reaction to the drug.

One of us (Herrold) has noted approximately the same efficacy of sulfanilamide in adult male patients that we obtained in children. In about one third of adult males results were highly satisfactory in that the patients were cured in a period of from ten to thirty days. In approximately another third of the patients response was fairly satisfactory and cure was obtained after from thirty to sixty days. In the remaining third the effect of the drug was unsatisfactory either because of the inability of patients to

continue the use of sulfanilamide as the result of the more serious side reactions, or the patients were refractory to the action of the drug.

SUMMARY

We treated gonorrheal vulvovaginitis by various methods prior to the use of sulfanilamide.

In a series of twenty-five patients who were given sulfanilamide, seven were cured in an average of 17.3 days and nine in an average of 42.9 days. Only two of the nine remaining patients were cured by additional administration of sulfanilamide.

A standard dose of sulfanilamide was used in all, the results suggest a comparative futility of the continuation of more than two standard courses of treatment.

The children have tolerated sulfanilamide extremely well as compared to adults, in whom reports have indicated a high incidence of reactions.

185 North Wabash Avenue

CARBON DISULFIDE POISONING

WITH A REPORT OF SIX CASES

SAMUEL T. GORDY, M.D.

AND

MAX TRUMPER, Ph.D.

PHILADELPHIA

With the rapid growth of the rayon industry a health hazard has reappeared—carbon disulfide poisoning. The United States is one of the largest rayon manufacturing countries in the world, having produced 290 million pounds in 1936. Of the twenty-five rayon factories with 50,000 employees now operating in this country, nineteen are viscose plants using carbon disulfide. For every 3 pounds of rayon produced, 1 pound of carbon disulfide must be used. In 1936 more than 33 million pounds of carbon disulfide was consumed by one large viscose corporation.

Foreign journals contain reports of many hundred cases of poisoning from carbon disulfide in viscose and rubber plants, yet in our own country this form of poisoning has received little attention in medical journals. For some reason the subject has been shrouded in mystery and to our knowledge only five reports have been made by American authors: Peterson¹ in 1892, Heath² in 1902, Jump and Cruick³ in 1904, Francine⁴ in 1905 and Hamilton⁵ in 1925. We ourselves have examined six cases and have knowledge of many more. With the application of the new occupational disease compensation laws in many of the states, more will be heard of this insidious poison.

The toxicology of carbon disulfide concerns itself principally with the incidence of disability to workers using this chemical solvent in some processes pertaining to rubber, in making explosives, as an insecticide, in extraction of fat from hides, bones, wool and vegetables, in the sulfur clearing of crude paraffin and especially in the manufacture of artificial silk (viscose). Historically the incidence of carbon disulfide poisoning roughly parallels the industrial uses of this compound in various countries. In 1843 Parkes's process

Carey⁹ of Boston treated two cases of gonorrheal vulvovaginitis in children with sulfanilamide and obtained prompt favorable results in both cases.

Our series includes a group of twenty-five children varying in age from 3 months to 10 years. Three of this group had chronic infections at the time of institution of treatment, one subacute and the remainder acute infections. No local treatment was used and sulfanilamide was administered orally in fruit juice to all the patients. The supply of sulfanilamide for this study was furnished by the Winthrop Chemical Company. A standard dosage was used throughout.

TABLE 1—Dosage of Sulfanilamide

| Days | Dosage per Day |
|---------------------------|---|
| 1st and 2d day | $\frac{3}{4}$ grain per pound |
| 3d to 7th day inclusive | $\frac{1}{4}$ of original dose or 9/16 grain per pound |
| 8th to 21st day inclusive | $\frac{1}{2}$ of original dose or $\frac{1}{8}$ grain per pound |

During the first two days the daily dosage was three-fourths grain (0.05 Gm.) per pound of body weight in four equally divided doses at intervals of six hours. During the next five days the dosage was reduced to three-fourths of this amount or nine-sixteenths grain (0.04 Gm.) per pound daily. During the second and third weeks the dosage was reduced to three-eighths grain (0.024 Gm.) per pound daily or one-half the initial dosage. At the end of a three weeks course of treatment a rest period of one week was given regardless of the results of smear examinations. All patients whose smears were positive at the end of this rest period were given a second course exactly like the first. A rest period was also given at the end of the second course of treatment, and for the majority of patients who were still infected at the end of the second rest period a third course of treatment was prescribed. A few patients were given a fourth course of treatment after the third rest period. An outline of the dosage is given in table 1.

Results in this group of twenty-five patients are summarized in table 2. It may be noted that only seven patients were apparently cured during the first course of treatment, or under a period of twenty-one days. By apparent cure we mean a clinical disappearance of all signs of infection from the urethra, vagina, cervix and rectum, as well as negative smears from these areas. None of this group of seven were cured under a period of sixteen days, and the average was 17.3 days. Four of the group cured during the first course of treatment had acute infections, two chronic and one subacute. During the second course of treatment nine additional patients were cured between the thirty-fifth and forty-ninth day of treatment, with an average of 42.9 days. Seven of the nine patients not cured were given a third course of treatment, and one of this group was cured during the third course or in sixty-three days. Four of the six remaining patients not yet cured were given another course of treatment after the usual rest period, and only one of this group of four was cured by such additional treatment. Analysis, therefore, reveals that approximately two thirds of the patients were cured by one or two courses of treatment, after which there was a very marked drop in the percentage of benefit derived by a third and fourth course of treatment. It would seem then that patients who do not respond to two standard courses of treatment have

gonococcal infections that are relatively resistant to therapy with sulfanilamide.

It is well known that many patients with gonococcal vaginitis, who are thought to be cured by the standard methods of examination, will have recurrence after a variable period. All patients in this group were kept in the hospital for two weeks after negative smears were obtained and all those listed as cured had follow up examinations from one to three months after discharge from the hospital.¹⁰ The examinations revealed that they were symptomatically normal, and smears were negative for gonococci. One patient who was examined after discharge from the hospital was found to have had extracellular diplococci but no discharge in the vagina and she is not included in the group of eighteen of this series who are listed as cured.

Negative smears will be found in many patients during the treatment or for a period of from three to seven days after the discontinuance of sulfanilamide. On the other hand, it was exceptional for patients to have a recurrence if they were clinically and microscopically normal for a period of two weeks after discontinuance of the drug. Smears were taken in a routine manner through the vaginoscope and sent to two laboratories for examination.

All reports on the use of sulfanilamide in any substantial series of patients have included a varying sort of side reactions from mild to so severe that discontinuance of the drug seemed advisable. However, in our group of children the incidence of side reactions was strikingly less than in any comparable series of adults that have been reported. Gastrointestinal symptoms, which so commonly occur in adult patients, were entirely absent in this group of children. Only one patient had a typical "drug fever" reaction, which occurred on the tenth day and was associated with urticaria and swelling of the face. Two other patients had a slight fever of less than 100 F. One patient had a rather severe epistaxis, and three others mild epistaxis. A definite anemia occurred in only one patient. Clinically, the patient had no subjective symptoms, but unfortunately this was one of the patients whom we

TABLE 2—Patients with Gonococcal Vaginitis Treated with Sulfanilamide

| Course | Number of Patients | Number of Patients Cured | Average Number of Days to Cure |
|--------|--------------------|--------------------------|--------------------------------|
| First | 25 | 7 | 17.3 |

¹⁰ Since this paper was submitted all cases have been re-examined from four to six months after discharge from the hospital. All have been found to be symptomatically and microscopically cured.

COMMENT

While we appreciate that a larger percentage of patients might have been cured during the first course of treatment by a greater dosage of sulfanilamide, we wished to keep the amount of the drug administered within the limits of safety for ambulatory patients. In general, a large percentage of the patients with gonococcal vaginitis must be treated without hospitalization. Hageman¹¹ reported, in a series of sixty-eight children, a much greater incidence of complications than we observed in our series. Three of his series had gonococcal vaginitis, and the others miscellaneous infections. He mentions that cyanosis associated with methemoglobinemia was encountered in approximately 50 per cent of the cases treated. He also states that one in every six patients treated had fever between the seventh and tenth day after the institution of sulfanilamide therapy and that one half of the patients with a febrile complication had an accompanying morbilliform rash. He states in regard to dosage that, in general, 1 gram daily to 20 pounds (9 Kg.) of body weight was given in divided dosage at intervals of six hours. This is the same dose that we used for the first two days of treatment but, while Hageman does not state the duration of this dosage, it is assumed that it was continued during the duration of treatment, which could no doubt account for the high incidence of reactions as compared to our series with a schedule of decreasing doses.

It is well known that patients with gonococcal vaginitis may be clinically free from symptoms for months and then have an exacerbation with positive smears. We have noticed this during the past ten years following other forms of treatment, but, as a rule, there would be a substantial number with recurrence during a period of from one to three months following discontinuance of treatment. In this series after the use of sulfanilamide, there was but one patient of those considered cured when they left the hospital who later showed a positive smear but no clinical symptoms. All patients listed as cured had follow-up examinations after leaving the hospital, but most of them had two such examinations. Therefore, we feel that with an apparent cure two weeks after discontinuance of sulfanilamide there is less likelihood of a later recurrence than after the former methods of treatment, including endocrine therapy.

It is not known why certain patients, on a like dosage, do not respond favorably to the administration of sulfanilamide. It seems noteworthy that in our series there were two girls from the same family, one of whom was cured in twenty-one days, while her sister failed to be cured after three courses of sulfanilamide. It is likely that these two children had the same type of gonococci, so that in this instance at least, primary serologic types were not an explanation of the difference in the clinical reaction to the drug.

One of us (Herrold) has noted approximately the same efficacy of sulfanilamide in adult male patients that we obtained in children. In about one third of adult males, results were highly satisfactory in that the patients were cured in a period of from ten to thirty days. In approximately another third of the patients response was fairly satisfactory and cure was obtained after from thirty to sixty days. In the remaining third the effect of the drug was unsatisfactory either because of the inability of patients to

continue the use of sulfanilamide as the result of the more serious side reactions, or the patients were refractory to the action of the drug.

SUMMARY

We treated gonorrheal vulvovaginitis by various methods prior to the use of sulfanilamide.

In a series of twenty-five patients who were given sulfanilamide, seven were cured in an average of 17.3 days and nine in an average of 42.9 days. Only two of the nine remaining patients were cured by additional administration of sulfanilamide.

A standard dose of sulfanilamide was used in all, the results suggest a comparative futility of the continuation of more than two standard courses of treatment.

The children have tolerated sulfanilamide extremely well as compared to adults, in whom reports have indicated a high incidence of reactions.

CARBON DISULFIDE POISONING

WITH A REPORT OF SIX CASES

SAMUEL T. GORDY, M.D.

AND

MAX TRUMPER, Ph.D.

PHILADELPHIA

With the rapid growth of the rayon industry a health hazard has reappeared—carbon disulfide poisoning. The United States is one of the largest rayon manufacturing countries in the world, having produced 290 million pounds in 1936. Of the twenty-five rayon factories with 50,000 employees now operating in this country, nineteen are viscose plants using carbon disulfide. For every 3 pounds of rayon produced, 1 pound of carbon disulfide must be used. In 1936 more than 33 million pounds of carbon disulfide was consumed by one large viscose corporation.

Foreign journals contain reports of many hundred cases of poisoning from carbon disulfide in viscose and rubber plants, yet in our own country this form of poisoning has received little attention in medical journals. For some reason the subject has been shrouded in mystery and to our knowledge only five reports have been made by American authors: Peterson¹ in 1892, Heath² in 1902, Jump and Cruice³ in 1904, Francine⁴ in 1905 and Hamilton⁵ in 1925. We ourselves have examined six cases and have knowledge of many more. With the application of the new occupational disease compensation laws in many of the states, more will be heard of this insidious poison.

The toxicology of carbon disulfide concerns itself principally with the incidence of disability to workers using this chemical solvent in some processes pertaining to rubber, in making explosives, as an insecticide, in extraction of fat from hides, bones, wool and vegetables in the sulfur clearing of crude paraffin and especially in the manufacture of artificial silk (viscose). Historically the incidence of carbon disulfide poisoning roughly parallels the industrial uses of this compound in various countries. In 1843 Parkes's process

for the cold vulcanization of rubber was introduced into France. Carbon disulfide was recognized by the French as an industrial poison as early as 1851, and workers were warned of its danger if the processes were carried on without proper ventilation. Duchenne de Boulogne⁶ is credited with first having reported polyneuritis from this cause. Delpach⁷ made the first significant and systematic study, reporting twenty-four cases, and supplemented these with animal experiments, which confirmed carbon disulfide as the causative toxic agent. He established carbon disulfide intoxication as a distinct clinical concept and established the basis for its differentiation from such contemporary neurotoxic syndromes as those arising from alcohol and lead, he gave it the name of carbon disulfide neurosis (nevrose sulphocarbonée). Delpach remarked that the severity of the resulting disorder bore no necessary relationship to the apparent acuteness of the onset of symptoms. He attempted to classify the chaos of symptomatology that the observed cases presented. Out of the melange of acute symptoms he divided his "acute" cases into two periods, the first a period of excitation and the second a period of collapse. The first period he described as one marked by an "exaltation of the intellectual faculties" and noted especially that sexual stimulation occurred with some degree of frequency. The second period, by contrast, consisted in general of a reversal of the picture with dulness, torpor and confusion dominating the picture. As the industrial use of carbon disulfide grew, further reports were added to the literature from England and Germany. Laudenheimer's⁸ monograph in 1899 containing more than fifty cases reenphasized the psychiatric aspects of this disorder in which Delpach had pioneered.

Until the introduction of artificial silk, the rubber industry was the principal origin of carbon disulfide poisoning. Thereafter from Germany, France, Holland and Italy have come the majority of reports. For example, in 1928 carbon disulfide poisoning ranked second in frequency in industrial disorders in Germany (Sommerfeld⁹). With the exceptions mentioned it is remarkable that there have been relatively few case reports of this disorder in America. However, it must also be remembered that industrial diseases in America have not had and do not have the emphasis or study which obtains in many European nations, where they are reportable and compensable.

The mode of entrance of carbon disulfide into the body is principally by inhalation of its vapor. Less frequently it is taken in by contact of the skin with the liquid, producing a sensation of burning followed by anesthesia. Prolonged contact produces second and third degree burns with blistering and a local neuritis.¹⁰ Lecousse and Derville¹¹ report a case in which a woman, aged 30, accidentally drank half a glassful of a mixture of carbon disulfide and carbon tetrachloride. The immediate symptoms were burning in the pharynx and esophagus and painful throbbing in the temples, marked redness of the face and slight dimness of vision.

Within three hours vomiting and diarrhea began and then there were complete inertia, a vacuous expression to the face and deep narcosis for two hours. As she came out of her coma she had marked stiffness of the jaws and anarthria, with persistence of vomiting and diarrhea. Several hours later she recovered her speech. She then described her sensations. She felt that the end of the world had come, she had painful and terrifying dreams, she had visions of the various members of her family rolling down to a steep precipice. She did not have a period of excitement or of drunkenness in the development of the symptoms of intoxication.

Poisoning may occur in two forms—the acute and the chronic. In the acute form the worker inhales the vapor in considerable concentration such as may occur when a container of the chemical is broken accidentally and the worker cannot escape in time or when workers are required to clean out vats in which it has been stored and the vats are not fully aired beforehand.

The chronic form, in which the worker is exposed to its vapors in small concentration usually for months, sometimes for years, is by far the more frequent form.

The chemical pathology of carbon disulfide poisoning is well understood. The pathologic changes depend on the solubility of lipoids in this agent. Since the biologic structure and physiologic function of neural tissue are so very dependent on the lipid setup in its cytoplasm, nerve fibers and myelin sheaths, it can be readily appreciated that lipid solvents which are introduced within the body will give evidence of their action primarily with neurotoxic manifestations. Carbon disulfide poisoning therefore belongs to the pharmacotoxicology of narcotic poisons such as ether, chloroform and alcohol. It is a specific cerebral and neural poison and in its acute phases produces narcosis and paralysis after preliminary excitation.

In experimental animals (Poincaré,¹² Lehmann,¹³ Koester¹⁴) poisoning may produce irreparable changes in the central and peripheral nervous systems, with changes in the ganglion cells, myelin sheaths and axon cylinders—at first increased irritability, then diminished excitability and finally irreversible degenerative changes. The toxin cannot be said to be selective in its action on any particular centers or areas, but in general the gray matter suffers most heavily. In the brain diffuse softening with breaks in the pathways occurs, and also in the cord with dissolution of the myelin. Degenerated cells are found in all portions of the brain, hence the protean character of the symptoms. In experimental animals there are in addition fatty degeneration of the heart muscle and dilatation and rupture of cerebral vessels. Wiley, Huepner and von Oettingen¹⁵ reported extensive degeneration of the testicles in their animals.

The effects on such animals may be divided into three groups, narcotic, irritable and paralytic. The narcotic phenomena are torpor, dulness, semitorpor and muscular weakness. The phenomena of irritability are incoördinate movements, muscular twitching, vomiting, muscular cramps and disturbance of vaso-motor centers. The paralytic symptoms in both animal and man are disappearance of tendon reflexes, muscular

palsies, respiratory and cardiac paralysis and death. There are no especial hemolytic phenomena.

While acute death has occurred in some of the cases of carbon disulfide poisoning it is relatively infrequent. There is a dearth of autopsy material in man and it is necessary to depend to a large extent on the studies in animals for the demonstration of the pathologic changes that result. Recently, however, Abe¹⁶ reported a case of carbon disulfide poisoning of thirteen years' duration in a young man who was employed in mending rubber shoes. After headache, malaise, anorexia, depression, irritability and neurasthenoid symptoms of long standing, a psychosis of the Korsakoff type developed, with loss of memory, retrograde amnesia with confabulation, speech disturbance, weakness of the legs, urinary disturbance, Romberg and Babinski signs, muscular cramps, marked tremor, edema of the legs, high fever and albuminuria (a diagnosis of uremia had been made). Death occurred after ten months of severe symptoms, and the autopsy elucidated the entire clinical picture. The microscopic examination showed regressive changes in the nervous system in addition to fatty degeneration of all the other organs. There was no evidence of any acute inflammatory process in the vascular areas of the nervous system (no polymorphonuclear leukocytes anywhere nor any evidence of chronic inflammatory vascular change). The fatty degeneration of the nervous system was mostly central and not strikingly peripheral. The degenerative changes in the cerebral cortex were of such wide distribution as to be independent of the vascular supply and independent of any presumed chronic vascular damage. The damage was especially marked in the gray matter of the cerebrum, cerebellum and brain stem, while the white matter by contrast was almost free from change. There was marked degeneration of the pyramidal tracts in the pons, extending into the cord. The degenerative changes of the neurons and myelin sheaths showed evidence of a mixture of recent and long standing toxic damage of both moderate and severe degree. These changes were attributed to direct toxic damage and also were nutritional in origin.

In man the symptoms of acute poisoning are malaise, headache, vomiting, vasomotor disturbances, muscular cramps, motor unrest, excitement, unconsciousness and motor palsies. Floret¹⁷ reported three cases of so-called acute poisoning. In one case the person inhaled the concentrated vapor of carbon disulfide for a few minutes. Unconsciousness resulted almost immediately. For a year following this she was pale, lacked appetite, vomited and had tremor of the hands. Later epileptiform seizures, muscular twitching and gastrointestinal disturbances occurred. Gastric analysis showed diminished hydrochloric acid. After longer exposure in the same room as this patient, and after inhaling more concentrated carbon disulfide vapor, two other persons reacted similarly. In addition to loss of consciousness there were episodes of laughter and weeping, disordered heart action and muscular twitchings. After several weeks one showed improvement from gastrointestinal symptoms but the other had epileptiform seizures under excitement.

In chronic poisoning three syndromes may be differentiated which frequently come together, (1) somatic disorders, (2) organic disturbances of the central nervous system, (3) psychic disorders.

Symptoms of general somatic character are weakness, loss of appetite, diarrhea or obstinate constipation, loss of weight, simple quantitative anemia (with no change in the blood picture), bradycardia, tachycardia or arrhythmia, weakness of the limbs, pallor, cachexia, an ashen gray appearance of the conjunctiva, a primary increase in libido and later diminution and loss of sexual function (Constensou¹⁸ and Heim,¹⁸ Quarelli¹⁹). A syndrome resembling Addison's disease has been reported by Devoto.²⁰ He describes the case of a young physician whose research work in the fat extraction of chick embryos exposed him for six hours to an atmosphere heavily laden with the vapors of carbon disulfide. At the end of the day severe headache, dizziness, malaise and loss of appetite developed and he could not return to the laboratory the next day. Marked weakness developed, he was confined to bed and the third day jaundice developed. Within two weeks there was enlargement of the liver, secondary anemia and dark brown spots in the mouth and increasing weakness. Within a month typical symptoms of Addison's disease developed with arterial hypotension, pigmentation of the skin and progressive asthenia. Death occurred two and half years later. In view of the prior health of the young physician the author ascribed the Addisonian picture to damage done the adrenals by the toxic action of the inhaled carbon disulfide, with a simultaneous effect on the cells proper, the nerve ganglions and the capillaries, with an immediate disruption of function and subsequent sclerosis and atrophy of the organ. There was no autopsy, but the authorities regarded him as industrially incapacitated by carbon disulfide poisoning and after his death his family was compensated accordingly.

Weise²¹ analyzed the gastrointestinal symptoms in 100 cases, thirty-two being cases of chronic carbon disulfide poisoning from the rubber industry and sixty-eight of combined chronic hydrogen sulfide and carbon disulfide poisoning among workmen in the manufacture of artificial silk (viscose method). The men had worked an average of twenty-five months in these industries. In most of these cases a disturbance of the function of the stomach was noticed by the workmen within eight to nineteen months after beginning work in these industries. In 14 per cent of these cases, ulcers of the stomach or of the duodenum were diagnosed and in several cases operations were performed. In an additional 11 per cent, ulcers were suspected.

The morbidity statistics from several large artificial silk factories indicate an incidence of stomach trouble of 17.7 per cent from exposure to carbon disulfide and hydrogen sulfide, while all other textile factories show but 2.7 per cent. In the case of ulcers of the stomach or of the duodenum, the figures were 2.6 and 3 per cent.

ORGANIC NEUROLOGIC MANIFESTATIONS

According to Ranelletti, - 80 per cent of his cases showed neurologic symptoms. Those encountered are

headache, dizziness, severe occipital or frontal headache, pain in the limbs, increase or diminution in superficial and deep reflexes, incoordination tremor (a coarse intention or a static tremor), palsies or weakness of various cranial and spinal nerves, especially the facial, involvement of the optic tracts, muscular weakness, especially the flexors of the hands and feet, hyperesthesias, paresthesias, muscular twitchings or a polyneuritic syndrome (Duchenne de Boulogne,²³ Harris,²³ Bonhoeffer²⁴), disturbances of the intestine and bladder and parkinsonian syndrome (Ando-Gionotti,²⁵ Negro,²⁶ Quarelli²⁷). There may be alteration of irritability with paresis of the muscles. The combination of headache, visual disturbance and gastrointestinal disorders may simulate brain tumor.²⁸

Of special note are eye symptoms, which appear early—fatigability at near vision, diminution of visual acuity, distortion of images, colored rings about objects, fogging, scotomas, retrobulbar neuritis and pallor of the temporal disks (Monbrun, Richet and Faquet,²⁹ Monbrun and Faquet,³⁰ Nectoux and Gallois,³¹ Krause³²).

PSYCHIC DISTURBANCES

In fully half of the reported cases there was mental disturbance of much severity, varying in degree and persistence such as to be outstanding. Delpuch drew attention to the similarity in behavior in some of his cases to that of acute alcoholic intoxication. He used the term "ivresse sulphocarbonée" to describe the tipsiness, overtalkativeness and unmotivated happiness or joy which he observed or which were described by the fellow workers of some of his patients. Laudenheimer observed that "the psychic changes may appear with slightly preceptible but with increasing intensity over a period of several days," showing a definite prodromal period. "One is confronted with a lack of inhibition (ausgelassenheit)." There may be excitement and increased psychomotor activity, flight of ideas, outbreaks of irritability and unmotivated rage. On the other hand there may be somnolence, semistupor or simply forgetfulness and retardation and intellectual impairment.³³ Periods of amnesia, sleeplessness, sleep reversal, horrible dreams and anxiety states may precede the onset of definitive psychosis. The psychoses may be characterized by a definite manic depressive picture with either manic or depressive symptoms or an agitated depression. Visual and auditory hallucinations and delusions of persecution may color the picture, delirium may occur or a schizophrenic syndrome with catatonic excitement. A simple dementing process may develop with quantitative mental loss, without other striking features. The preponderance of patients exhibited varying degrees of mental impairment with torpor, hebetude, inability to concentrate, memory

defects and irritability even when psychosis did not become full blown. One of Peterson's³⁴ patients who had the delusion that his tongue and lungs were gone nevertheless comprehended the falsity of his belief. Clinically there is marked resemblance between carbon disulfide poisoning of low grade chronic type and asthenia or neuralgia. In cases in which the symptomatology is not advanced or dramatic in its manifestations its general features may be mistaken for neurasthenia and its local manifestations for various neuralgias. This is especially true if the neurologic signs are larval, inconstant or evanescent or do not correspond to any definite syndrome. Similarly psychic symptoms may be mild, neurasthenoid or hysteriform.

In 1888 Charcot,³⁵ in one of his *Leçons du Mardi*, presented a case of alleged hemiplegia in a rubber worker due to carbon disulfide. He demonstrated that neither the paralytic signs nor the sensory changes fitted in with the usual picture of hemiplegia or hemianesthesia. He made the comment that there was in Delpuch's and in later reported cases an insufficiency of real clinical evidence supported by neuropathologic changes to warrant these cases being called hemiplegia. Both Charcot and Marie³⁴ regarded the incongruity and heterogeneity of signs and symptoms as proof of their hysterical origin, especially in view of the coexistence of sexual disturbance. The power and persuasiveness of Charcot's psychiatric philosophy were sufficient for the time, to cast doubt on the value of the neurologic and psychiatric observations of Delpuch, an able hygienist and industrial toxicologist of a previous generation. While Charcot admitted that there were disorders of the central nervous system definitely ascribable to the action of carbon disulfide, he felt that a differentiation should be made between the organic neurologic damage, measurable by clinical analysis on the one hand, and the symptomatology, much of it of a psychiatric nature, imponderable and nonspecific on the other. The signs and symptoms of any neuropsychiatric disorder which did not in his opinion conform to a well defined clinicopathologic disorder were ipso facto hysterical in nature. With inexorable logic he applied the same criteria to other toxic agents, namely, alcohol and lead. Just as there could be traumatic epilepsy, there could be traumatic hysteria (neurosis). By the same token he held that there was a lead hysteria, an alcoholic hysteria, a carbon disulfide hysteria. In other words, hysteria was the common denominator of the bizarre, the incoherent and the disturbing elements which prevented the exacting clinician from fitting the patient into the contemporary neuropathologic scheme of things. Since hysteria according to Charcot, was such a common disorder he felt justified in denying the specificity of the action of carbon disulfide and declared that this substance, in common with alcohol and lead and trauma, was merely an *agent provocateur* of hysteria. Charcot's masterful clinical judgment, however, could not be dulled by too close an adherence to his own logic, for he expressed the opinion that hypnotism could not be expected to do much for this type of hysteria. This is practically a tacit admission that the usual form of hysteria was different from this type.

From a modern point of view one can look on the neurasthenoid and hysteriform symptoms as the primary response of the organism to a disruption in the internal milieu and a disorganization of the relative chemical stability of the neurons of the higher cerebral centers.

and association pathways and the vegetative nervous system with its adrenal connections

These early psychic symptoms are either irritative in character or a resultant of the suppression of the usual inhibitory functions of these higher centers, or a mixture of the two. If the toxic action is further continued, one has evidence of psychotic behavior. The result is not only a quantitative matter, in the sense of the amount of toxin absorbed, but qualitative in the sense that any or many cerebral areas may be simultaneously or haphazardly affected. Major psychotic phenomena may be delayed for years, as in Abe's case in which a Korsakoff syndrome developed after thirteen years' exposure.

Three groups of symptoms, namely, the somatic, the neurologic and the psychic, have been noted. Generally characteristic of this diagnostically is the occurrence of symptoms of two and usually all three varieties. Differential diagnosis is to be made from chronic alcoholism, lead poisoning, neurosyphilis, brain tumor, polyneuritis of other origin and postencephalitic parkinsonism, so protean are the manifestations of carbon disulfide poisoning.

A word concerning prognosis. It depends on the age, general bodily health and promptness with which the poisoning is detected and the removal of the worker from the deleterious atmosphere. In many instances the somatic and neurologic disorders disappear after the workers are removed from exposure to the toxic agent. Brief exposure may, however, have long continued or permanent sequelae. Tolerance is not established or, if so, only rarely. On the contrary, there is an increased susceptibility to poisoning on further exposure. Women are more susceptible and show a greater incidence of psychic disorder. The psychosis may be permanent (Peterson, Laudenhimer, Koester, Abe).

REPORT OF CASES

We ourselves have seen the following cases

CASE 1—History—A C a woman aged 27, married ten years, the mother of three children aged 9, 7 and 3½ years respectively had had generally good health and no illness during her pregnancies. She had been working in the rayon industry for years as a reeler of artificial silk. The onset of the present illness was of the acute type. One day she handled spools of incompletely dried viscose. Symptoms began with violent headache, faintness and then loss of consciousness. Shortly before losing consciousness she remembers being very restless, weeping, screaming and laughing. After recovering consciousness she felt as though she had been beaten all over. A little later she spit blood and had bloody bowel movements. She was semiconscious and stuporous the greater part of that day. Since that time she has had repeated spells. They last from fifteen to twenty minutes and consist of headache and numbness in various parts of the body and her hands and feet feel as though they were asleep. She has auditory hallucinations, her eyes feel jump and twitchy, black spots dance before her eyes, she has cold sweats and is contrary. Her behavior apparently had been so erratic and bizarre that commitment to the state hospital was seriously considered. As a result of her mental abnormality she has been separated from her husband.

Physical Examination—The patient is somewhat thin, has a reddish blond complexion and her skin has a peculiar cyanotic hue, the color of heliotrope. During the examination this alternated with pallor showing vasomotor instability. The gastrointestinal and cardiovascular systems were essentially normal. The blood pressure was 110 systolic, 65 diastolic.

Neurologic Examination—The pupils were regular, somewhat dilated and reacted to light and in accommodation. Extraocular movements were normal, the conjunctivae were of a grayish pallor and there was corneal anesthesia. The cranial

nerves were normal, tendon reflexes were exaggerated, there was no clonus and the Babinski sign was not present, there was a suggestion of Troemner's sign on the right, there were no definite sensory objective signs with the exception of the fact that she seemed to be indifferent to pin pricks throughout the body.

The Wassermann reaction of the blood was negative. The blood count revealed hemoglobin 70 per cent, red blood cells 5,050,000, white blood cells 10,600. The differential smear was normal. Examination of the urine showed a trace of albumin and from 400 to 500 pus cells per low power field, otherwise the urine was essentially normal.

Summary—A woman worked for six years in a viscose plant and was subjected to acute exposure to vapors of carbon disulfide, marked symptoms of intoxication developed accompanied by and followed especially by severe psychotic episodes. Neurosomatic manifestations are a simple secondary anemia, vasomotor instability, corneal anesthesia and paresthesias. She has psychotic episodes characterized by hallucinatory phenomena.

CASE 2—History—D G a woman, aged 23, married, had been a viscose worker for eleven months. Dec. 23, 1933, while at work, she noticed that she felt dazed and her mind seemed to wander. She retired to the rest room for a short time and when she came back to work there was a return of symptoms. She began to laugh and cry and feel sleepy. She retired to the rest room again and reported to the nurse asking for a tablet of acetylsalicylic acid. When she returned to work her symptoms were worse and she wept continuously, she was taken home and became comatose and remained so for a week. Since that time and after immediate recovery from the acute phase she has had episodes, especially at the time of the menses, of patchy areas of dyesthesia over various parts of the body, headaches, a jumpy feeling in the head, a feeling as though her eyes would pop out of her head, blurred vision, and a sensation that the 'brain seems dull and flat,' and she is very irritable and states that she goes out of her senses for a period of about half an hour. The length of the attacks varies from half an hour to three hours.

Examination—Physical examination revealed acne of the face, but the results of the general somatic examination were essentially negative. Neurologically there were exaggerated tendon reflexes, there was no ankle clonus and the Babinski sign was not present, a generalized hypesthesia, poor vision of the right eye, pallor of the right optic disk and gross contraction of visual fields (retrobulbar neuritis) were noted.

The Wassermann reaction of the blood was negative. The blood count revealed hemoglobin 74 per cent, red blood cells 4,110,000, white blood cells 8,100. A differential smear was normal. Examination of the urine showed a trace of albumin and from 75 to 100 pus cells per low power field, otherwise the urine was normal.

Summary—In a woman worker in a viscose factory for eleven months, acute pseudo emotional disturbance and severe coma developed followed by episodes of headache, dyesthesia, visual disturbance, irritability, psychotic behavior and retrobulbar neuritis.

CASE 3—History—I W a married woman aged 33, the mother of two children aged 3 and 10 years had worked on and off in a viscose plant for about two years. On the same day as in the other cases headache and then inability to move any of her muscles developed. She was aware of her surroundings but was unable to talk. Objects about her appeared to become of tremendous size and then to become extremely small. She had to be taken home from the plant. She was unable to see until the next morning when she recovered her vision objects appeared to be distorted as though she were 'looking through smoggy glass.' She was unable to urinate for four days, her arms and legs went to sleep and she was unable to move them. She described herself as feeling as though she had been beaten severely all over her head. It was difficult for her to breathe and she felt as though she had asthma. When she felt respiratory difficulty some one gave her artificial respiration. Since then she has had episodes of numbness in her hands and feet, she feels as though her eyes vibrate and she has episodes of crying and sleeplessness. Her behavior

is peculiar and she often goes to sleep half dressed, is depressed and morose and is very susceptible to odors. Because of her behavior she was referred to and attended the clinic of the state hospital every week for three months. Physical examination and neurologic examination were essentially negative.

The Wassermann reaction of the blood was negative. The blood count revealed hemoglobin 80 per cent, red blood cells 4,650,000, white blood cells 9,200. The differential count was normal. Examination of the urine showed a trace of albumin, otherwise it was negative.

Summary—A woman viscose worker suffering from acute intoxication manifested headache, lilliputian and brobdingnagian visual hallucinations, amblyopia, distorted vision (wavy vision), paresthesia of the limbs with muscular weakness, paralysis of the bladder and respiratory embarrassment as immediate symptoms.

Following recovery from the acute phase, the residual symptoms are paresthesias of the limbs and eyes, emotional outbreaks, episodes of sleeplessness, depression, forgetfulness and larval psychotic behavior. Neurologic signs are absent.

CASE 4—History—C. A., a man, aged 42, worked in the rayon industry three years, much of his work consisting in the installation and repair of the ventilating system in a new rayon plant. Within the first six months he began to have symptoms, with two periods of greater severity. He began to have blurring of vision, pain and burning in his eyes, headache, "nervousness," a sensation of seasickness and occasional vomiting. He was unable to sleep or rest and later he had reversal of sleep and marked fatigability. He began to have episodes of depression, noticed by his wife as well as himself, and was extremely irritable toward his children. A feeling of stiffness and pain developed in his limbs, especially in the tendons of his legs, the sensation being described as feeling as though he had run a long race. His vision gradually diminished so that he had only light perception in his right eye. Visual images in the left eye appeared as though distorted by heat waves. About six months after he began this work he began to notice a progressive diminution in libido and episodes of general depression, beginning about the same time and continuing after he left the industry. His depression is at times relieved when he is actively occupied.

Examination—The right pupil is larger than the left, slightly irregular and reacts sluggishly to direct light but well consensually. The left pupil is fairly regular and reacts well to light. There is loss of vision over the nasal field of the right eye. The field of the left eye was not affected. The right eyeground showed a retinchoroiditis with marked blurring and loss of outlines of the nerve head. The left eyeground showed pallor of the temporal disk. There was corneal anesthesia, the ocular and palpebral conjunctivae of both eyes being thickened. Other cranial nerves were grossly normal. Muscular power was good throughout. There was hyperreflexia, no Troemner or Babinski signs, no ataxia, and no disturbance in any of the modalities of sensation, with the exception of generalized hyperesthesia. The cremasteric reflexes were considerably diminished. The skin showed dermatographia. The thoracic and abdominal viscera were normal. The blood pressure was 145 systolic, 85 diastolic.

Summary—A man, engaged principally in installation and repair of the ventilating system in a viscose plant, showed symptoms of chronic intoxication with blurring of vision (wavy vision), headache, nausea, vomiting, sleep reversal, fatigability, depression, neuritic pains, considerable loss of vision, retinobulbar neuritis, choroidoretinal pathologic changes and diminution of libido.

CASE 5—History—E. B., a woman, aged 32, was employed off and on for seven years in the rayon industry, the last time for a period of three years. She stopped work Feb. 21, 1934. For three months in 1933 she was in the reeling room for the last three months in 1933 in the coning room and for the first two months in 1934 in the reeling room.

After two months in the reeling room she began to have "nervous spells" which consisted of irritability and causeless weeping. She had sore throats and colds and she has not been free of bronchial trouble since, she has a constant sensation of rawness in the throat. She began to feel that she was

going crazy. She had frequent experiences in which she had lapses of memory, she would find herself some place and did not know how she had gotten there, for example, she would have a knife in her hand and would not remember how it had occurred. Frequently at work she would have surges of causeless rage and she felt as though she would like to smash the reels. She had a strange sensation in her feet, she felt as though there was nothing underfoot when she walked, and severe dizziness and intense headaches developed. She had double vision and also "things appeared to have a wavy appearance." She was constantly apprehensive of going crazy and had frequent momentary flashes of unconsciousness. She had severe pain in the chest and felt as though her chest was in a vise and was being crushed. These episodes were so severe that she had to stop work for three or four months. She has a residual of this sensation at present under the right shoulder blade. She feels as though there is a hole in her chest and that she is blowing her breath through it. She is dyspneic. She had sensations in which she felt as though objects were moving down her arms and legs. She has had persistent chronic fatigue during which time she felt "dopy," and it did not lie down she would fall off her feet. Even now her spells of fatigue are so severe that she becomes indifferent to everything about her. She has had one cold after another. During the summer of 1934 she had severe dysmenorrhea every month with very black discharge (this condition was relieved by diathermy treatments).

During this time she had severe anorexia but her appetite has improved in recent months. When she feels better she is able to do her housework but frequently is so fatigued for no reason at all that she cannot do it.

During one of the periods in which she was in the converting department she had to write the simplest things down because her memory was so defective. For two years while she was working and after she stopped working she has been unable to sleep well. Since that time she has lost all sexual desire.

Examination—The patient is rather tall, fairly well built and is fairly alert and answers questions intelligently. She weighs 170 pounds (77 Kg.).

The pupils react to light and in accommodation, extraocular movements are normal. There is bilateral corneal anesthesia. The pharyngeal reflex is absent. The pharynx is pale with hyperemic spots (chronic pharyngitis). The cranial nerves are otherwise normal. There is no ataxia and no evidence of cerebellar dysfunction except for a slight Romberg sign. The biceps, triceps, knee and ankle jerks are present and active. There is no disturbance in any of the modalities of sensation.

The Wassermann reaction of the blood is negative. The blood pressure is 98 systolic, 70 diastolic.

Summary—In a woman who worked with viscose, subjected to chronic exposure to vapors of carbon disulfide, the following symptoms developed: crying spells, causeless rage, double vision, vertigo, intense headache and oppression of the chest, paresthesias, corneal anesthesia, chronic fatigue, loss of weight, defective memory, loss of libido, hypotension, irritability, chronic irritation of the mucous membranes of the nose and throat and mental phenomena consisting of petit mal episodes.

CASE 6—History—E. S., a man, aged 49, foreman in a viscose factory who worked principally in the reeling room first became ill in April 1933. Headache, vertigo, rapid loss of weight and paresthesia in his hands and feet developed. With this there was also insomnia, causeless weeping and night terrors, he had achiness in his bones for months. For some time he felt that his mind was not working properly. Both his wife and his son have noticed that his actions have not been normal and have told him about his crying and screaming while sleeping and that his body shakes all over. His memory is unreliable. He describes episodes resembling fugues in which he finds himself at some place and can't remember how he got there. He is now unable to drive a car because he is uncertain of himself. He complains of dyspnea and a sense of oppression in the chest. He also has episodes of blindness lasting for a few minutes and also double vision. He is unable to retain a position because of his memory faults. He has a marked diminution of libido.

Examination—The patient is fairly well built and gives evidence of having lost weight, his present weight being 156 pounds (71 Kg). The pupils are regular and react to light and in accommodation, the eyegrounds show slight pallor of the temporal disks and slight atherosclerosis. The cranial nerves are otherwise normal except for mild tremor of the tongue. There is no ataxia or other evidence of cerebellar dysfunction. The biceps, triceps, knee and ankle jerks are present and equal, there are no pathologic reflexes and no disturbances in any of the modalities of sensation.

The blood pressure is 150 systolic, 100 diastolic.

Mental Status—The patient tends to be morose, apathetic and somewhat indifferent and his thought processes are retarded. He is oriented in all spheres but his memory is definitely dulled. He finds it difficult to place various occurrences in the past in any sort of proper sequence. He formerly had the reputation of being a first class worker and had the ability of handling other employees, now he has a marked lack of initiative and a sort of childlike dependence on others.

Summary—A man who worked with viscose and was subject to chronic exposure to carbon disulfide fumes acquired headaches, vertigo, loss of weight, paresthesias, insomnia, causeless weeping, night terrors, fugues, petit mal episodes, depression, impairment of memory, loss of initiative and impairment of libido. The neurologic examination was negative.

COMMENT

These six cases may be divided into three so-called acute and three chronic forms of this disorder. In all six there is a relative paucity of neurologic signs. Two patients showed corneal anesthesia. The visual disturbances are noteworthy, two patients complained of what might be termed "wavy vision," two had retrobulbar neuritis, and in one acute case lilliputian and broodingnagian hallucinations (or illusions) were present. As far as we are aware, "wavy vision" and this type of hallucination has hitherto not been reported in carbon disulfide poisoning.

Especially noteworthy is the periodic or cyclic character of psychotic episodes accompanied by a variety of paresthetic or hallucinatory phenomena, which were sequelae in four of the cases. Chronic fatigue and asthenia is present in two of the cases, amnesic features in two and progressive mental deterioration with memory defects in one of the cases. In four there is diminution or loss of libido. All of the patients are invalids.

Two and one-half years ago we urged the federal authorities of the need for a survey of the toxic hazards in the viscose industry. More recently, Dr Adele Cohn³⁵ in her Bryn Mawr survey found thirty cases of psychosis which developed in one viscose plant. At present a federal survey of the rayon industry is being made which will be of inestimable help to all who are interested in the prevention, early diagnosis and treatment of carbon disulfide poisoning.

The mode of action of carbon disulfide is clear, it is hypotrophic and hence neurotoxic. This is to be inferred a priori from its physicochemical properties, it is demonstrated by the pathologic material in experimental animals and in man. Until a few years ago most authorities relied on the quantitative experimental work of Lehmann on animals. His rats did not tolerate an atmosphere containing 1 mg of carbon disulfide per liter of air for an eight or nine hour exposure. The inspection service of the British factory department³⁶

in 1934 still uses these figures³⁷ and states that "an atmosphere of 322 to 386 parts per million produces slight symptoms after several hours, and 483 to 802 parts per million is the maximum concentration that can be inhaled for one hour without serious disturbance." As a footnote the carbon disulfide memorandum adds that "these are for acute effects, exposure of several hours a day to concentrations lower than those mentioned leads in a short time to chronic poisoning." No definite figures are given for chronic exposure.

Wiley, Hueper and von Oettingen in their 1936 experiments on rats and mice have demonstrated that the permissible upper limit is 0.1 mg per liter (32 parts per million) for exposures longer than Lehmann's.

Zhitkova³⁸ in 1933 reports that a total of 5 mg has induced poisoning in man and further states the upper limit of safety as 0.01 mg per liter of air to be the official standard of the Soviet government.

Voltmer and Nuck³⁹ in 1933 reported a survey in which simultaneous studies were made of atmospheric working conditions and physical examinations of workers in a rubber factory in Germany where carbon disulfide was used. Sampling of the air repeatedly showed figures below 1 mg per liter of carbon disulfide concentration, at times as low as 0.2 or 0.1 mg per liter. Of fifty-seven women workers employed for from five months to twenty years, only six were free of symptoms and signs of illness. All complained of fatigue and 70 per cent suffered from visual and gastrointestinal disturbances. From 20 to 40 per cent complained of headache, nausea, vomiting, memory defects and sensory disturbances including dysesthesias. This clinicotoxicologic study is one of the few that indicate chronic toxicity levels.

Two factors of importance complicate the translation of results of experimentation on animals to man, especially in chronic intoxication.⁴⁰ The first is the imponderable one, namely, that there can be no psychopathologic changes in animals with the exception of apes or conditioned animals. The vast panorama of neuropsychiatric symptomatology in carbon disulfide poisoning can be only partially illuminated by animal intoxication. The other factor that seems to have been neglected is the relationship of the weight of the nervous system, particularly the cerebrum, to the total body weight of animals in contrast to that of man. Human neural tissue with its vascular supply is capable of absorbing and fixing a relatively greater quantity of circulating neurotoxin than the nervous system of animals.

Our knowledge is sufficient for the establishment of minimal health standards of carbon disulfide in industry. Until such standards become established, in our opinion, the concentration of carbon disulfide in the atmosphere must be kept well below 0.1 mg per liter of air, preferably around 10 parts per million (0.03 mg per liter). In addition, frequent examination of workers must be maintained to detect the early symptoms of chronic poisoning.

856 North Fifth Street—921 Medical Arts Building

³⁷ One mg of carbon disulfide per liter of air equals 322 parts per million at 25°C (Haggard and Henderson: *Toxic Gases*).

UNDULANT FEVER

ITS TREATMENT WITH SULFANILAMIDE

ROBERT L. STERN, M.D.

AND

KEN W. BLAKE, M.D.

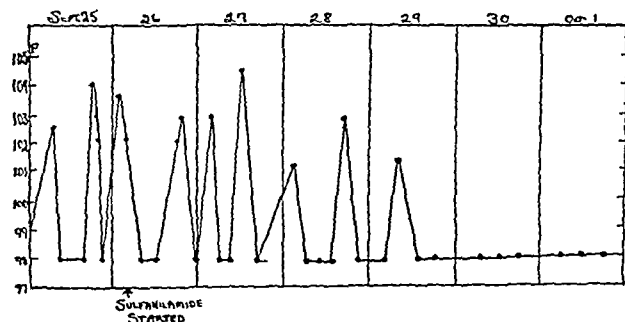

LOS ANGELES

The medical treatment of undulant fever has not included, as yet, any drug of relative therapeutic safety that is specific *in vivo* against the causative organism of the disease *Brucella melitensis*.

Brucella melitensis, originally known as *Micrococcus melitensis*, is pleomorphic; its morphology in part determined by the culture medium or the preparation used for its study. Morphologically it is considered variously by several authorities¹ on bacteriology to be a coccus, a bacillus or a coccobacillus. On this basis, with the effect of the drug in question established against certain other pathogenic bacterial forms, we, working independently, gave sulfanilamide in therapeutic doses to each of three private patients suffering from clinically and serologically established undulant fever. The following highly satisfactory and prompt results are reported.

REPORT OF CASES

CASE 1—Miss M. R., white, aged 24, a movie actress, first seen by R. L. S. Sept. 5, 1937, stated that she had been in good health until September 3 when she felt feverish and chilly and had generalized muscular aching. The next day these symptoms continued and she also experienced a moderate

Temperature in case 1

frontal headache and stuffiness in the nose. In the afternoon her fever peak was 103 F. An inventory by systems revealed no other complaints. She had never experienced a serious illness or operation, but three weeks previously she had a tooth extracted with subsequent vague aches and a temperature to 101 F for three days. The patient was well developed and well nourished; she appeared feverish and was perspiring profusely. The afternoon temperature was 102 F, the pulse rate 100 and the respiratory rate 20. The blood pressure was 110 systolic 70 diastolic. Thorough physical examination revealed no abnormalities other than slight enlargement of the anterior cervical lymph glands and some tenderness of the leg muscles. The urinalysis revealed normal conditions. The Wassermann reaction was negative. Study of the blood showed the erythrocyte count to be 4,520,000 per cubic millimeter of blood and the hemoglobin 83 per cent. The leukocyte count was 6,100 per cubic millimeter of blood with a differential count of 68 per cent polymorphonuclear neutrophils, 2 per cent polymorphonuclear eosinophils, 26 per cent small lymphocytes and 4 per cent monocytes. Several subsequent examinations of the urine and blood revealed the same essentially normal results. Despite conservative treatment with salicylates and supportive measures

the fever continued and at the end of two weeks a regular daily occurrence of afternoon chill followed by a temperature of from 102 to 104 F for several hours, with rapid subsidence to normal in the early evening hours, had been established. During the morning she felt perfectly well and had no fever. Except for severe night sweats she had no other symptoms or complaints. Her appetite remained excellent and she ate heartily, according to instructions, so that despite the continued fever no loss of weight occurred during her illness. During this period physical examination had failed to reveal any additional abnormal changes except a marked coating of the tongue, halitosis, the daily fever and profuse sweats. At the end of the second week the peculiar pungent odor of the perspiration first gave the impression of probable undulant fever. X-ray examinations of the chest had revealed no abnormalities. Culture of the blood had remained sterile. Culture of the stool had revealed no growth of typhoid or dysentery bacilli. In the third week agglutination tests for the typhoid and paratyphoid group of organisms were negative but the agglutination for undulant fever was found to be strongly positive in dilutions to 1:1,280, beyond which it was not carried. A temperature chart was kept, during the second and third weeks it disclosed daily rises of from 102 to 104 F. As soon as the diagnosis was established, on the twenty-first day following the onset of symptoms, the patient was started on a regimen of sulfanilamide, which included 40 grams (26 Gm) the first day, 60 grains (4 Gm) the second, 80 grains (5.2 Gm) the third, 40 grains the fourth and then 20 grains (1.3 Gm) daily for one week more, each day's total in divided doses. During this period all other drugs were stopped. For the first three days the fever and chills continued, but on the fourth day after a noon rise of temperature to 101 F for one hour, the lowest peak in two weeks the temperature dropped to normal, and from then on no further chills or fever were experienced. At the patient's last visit, six weeks after becoming symptom free she continued to feel very well and weighed 6 pounds (2.7 Kg) more than she had at the onset of illness. Her source of infection was apparently raw milk bought from a "fly by night" dairy which had changed hands several times during the past four months.

CASE 2—T. S., a man aged 47, a miner, first seen by R. L. S. Oct. 5, 1937, stated that he had felt perfectly well until Aug. 5, 1937, when general aching and fever developed. He consulted a physician, who told him that he had some congestion in the lungs. He was able to be up and about but continued to have a daily fever and felt poorly. During the latter part of September he went to the desert and attempted to work but suffered a severe exacerbation of symptoms. For one month before he was seen here he had severe daily chills, an afternoon fever accompanied by drenching sweats and almost constant backache. Between the chills he felt fairly well. He had lost 20 pounds (9 Kg) at the onset he had a "severe cough" which when first seen had eased to his usual "cigarette cough." An inventory by systems revealed no other complaints. The only relevant past history was gonorrhea in 1911 and a hemorrhoidectomy in 1934. He had eaten at several restaurants and hotels during the month previous to his illness but had ingested no known raw or goat's milk. The patient was gaunt and appeared exhausted; he perspired freely on exertion and had a short, loose cough. The afternoon temperature was 99.8 F, the pulse rate 88 and the respiratory rate 18. The blood pressure was 118 systolic 80 diastolic. The observations were otherwise essentially negative with the exception of injected sclerae and a few variable coarse rales in each lung base. A blood count gave normal results. Urinalysis showed a trace of albumin but was otherwise essentially negative. Fluoroscopy of the chest revealed only heavy bronchial markings. A tentative diagnosis of undulant fever was made and the patient was given salicylates and instructed to keep a temperature chart. A daily fever of from 99 to 101 F was recorded each afternoon during the two day interval necessary for the agglutination tests. October 7 the results were returned disclosing a negative agglutination for the typhoid and paratyphoid group of organisms and a positive agglutination for undulant fever in dilutions to 1:1,280, beyond which it was not carried. On the basis of the experimental

Jordan, E. O. *A Textbook of General Bacteriology*, ed. 10. Philadelphia: W. B. Saunders Company, 1931, p. 60.

case 1, the patient was placed on a regimen of sulfanilamide. His weight was 167 pounds (76 Kg), he was, therefore given 60 grains the first and second days, 80 grains the third 40 grains the fourth and then 20 grains daily, each day's total in divided doses. All other treatment was discontinued. The drug was started on the evening of October 8. On October 12 he reported that he had experienced no fever, chill or other ill feeling for the past twenty-four hours. He has subsequently remained well, with no elevation of temperature noted to the present time. The daily 20 grain dosage of sulfanilamide was continued for six days into the afebrile period and then a dosage of 15 grains daily was continued for six days more. Since the cessation of the fever the patient has regained 10 (45 Kg) of the 20 pounds (9 Kg) of weight lost. It was impossible to trace the source of the patient's infection since he had eaten in a number of establishments during the several months preceding the onset of symptoms.

CASE 3—H F, a white man aged 38 first seen by K W B at 3 p m on May 16, 1937, complained of the sudden onset of a chill and fever three weeks previously after having bathed in the ocean. He had since had a daily afternoon fever, reaching 103 F on several occasions. He was growing extremely irritable, nervous and depressed. Having been on a starvation diet at the direction of an osteopath he had lost from 15 to 20 pounds (68 to 9 Kg). A migratory 'twanging' pain which was noted in the abdomen was localized in the left upper quadrant at the time of this examination. Inquiry by systems revealed a severe constipation, for which laxatives had been taken daily for several years but he had no other complaint. He stated that he had been drinking raw milk from a small dairy for the past five years and had eaten much ice cream. He had no access to the handling of raw meats. His past history revealed a "nervous exhaustion" in 1931 but no other illnesses, operations or accidents. Typhoid vaccine had been administered while he was in the army in 1918.

The patient was tall thin extremely irritable and nervous. He appeared to be acutely ill. The temperature was 101.4 F, the pulse rate 84 and the respiratory rate 18. The skin was dry and warm and presented several small nevi over the anterior chest wall. Thorough physical examination revealed a dry and coated tongue, a few fine rales in the left base of the chest posteriorly and a diffuse tenderness in the left upper quadrant of the abdomen in the region of the spleen. The blood pressure was 122 systolic 82 diastolic. The observations otherwise were essentially negative. The erythrocyte count was 4,890,000 per cubic millimeter of blood and the hemoglobin was 85 per cent Sahli. The leukocyte count was 5,750 per cubic millimeter of blood with 64 per cent polymorphonuclear neutrophils, 3 per cent polymorphonuclear eosinophils, 31 per cent lymphocytes and 2 per cent monocytes. Urinalysis revealed a specific gravity of 1.025 and an occasional leukocyte but no albumin, sugar or casts. A macroscopic agglutination test of serum versus *Bacillus abortus* on May 18 revealed complete agglutination in dilutions from 1:20 to 1:5,120. The blood Wassermann reaction was negative. The patient was treated symptomatically until May 22, when a course of sulfanilamide was undertaken. During the following thirty-six hours he was given 105 grains (7 Gm) of the drug in 15 grain doses. Owing to the onset of a slight vertigo the administration was stopped at 9 p m. By the following morning the temperature was again normal where it has remained to the present time. He was able to return to his work one week later and when he was last heard from November 15 he had gained approximately 30 pounds (13.6 Kg) and had experienced no evidence of a recurrence. The only other drug used during this entire time was a mild barbituric sedative.

CONCLUSIONS

1 Three patients with undulant fever were treated with sulfanilamide in tablet form with prompt clinical cure of the disease during the administration of the drug.

2 The maximum dosage according to present standards appears to be necessary.

727 West Seventh Street—1930 Wilshire Boulevard

Clinical Notes, Suggestions and New Instruments

CHIN TO CHIN LOCKING OF TWINS

H E BOWLES M D HONOLULU HAWAII

This report has been promoted by a recent statement of Peters¹ to the effect that he has been unable to find a single report of interlocking of twins in American obstetric literature. Furthermore, he brings out the fact that the Index Catalogue of the Library of the Surgeon General's Office covering the years 1912 to 1932 lists only three articles referring to this obstetric complication. All these are in the Swedish literature.

According to von Braun, the accident occurred in Vienna once in 90,000 labors. Coleman² in 1935 reported two cases in each of which the two fetal heads attempted to engage in the pelvis simultaneously. A commoner type is the descent of one fetus as a breech. Various combinations are possible. Our case presented chin to chin, with the second fetus attempting to enter the pelvis before the head of the first had been delivered. Peters' case was of this type. In his case the anomaly was detected in time to save both the mother and the twins by cesarean section. If the mother and the babies are to be saved the diagnosis of locked twins must be made early. It is facilitated by a previous roentgenogram. Every case in which a plural pregnancy is suspected should be given this aid to diagnosis. For a discussion of various steps in delivery of locked twins, the reader is referred to obstetric textbooks, which usually cover the subject thoroughly.

REPORT OF CASE

The patient was delivered vaginally of twins with locked heads, chin to chin. The first child was a double footling, and the second presented by its head.

Miss R H, aged 19, a primipara Caucasian-Hawaiian, was seen at one of Honolulu's antepartum clinics twice prior to the onset of her labor. Her menstrual history had been negative. Her measurements were normal. The estimated date of confinement was December 25. Diagnosis of twins was not made by her physician during her two visits to the antepartum clinic December 11 and 18. Labor commenced about 8 p m December 26 and she remained at home until her admission to the hospital December 27 at 4:35 a m. Normal contractions continued with but little inconvenience. The membranes ruptured spontaneously at 11:15 a m.

The first inkling that there was anything peculiar about her case came at noon when a small fetus presented feet first. It was expelled as far as its shoulders. Nitrous oxide anesthesia was used at this stage. Strong contractions continued. Digital examination revealed a second fetal head and the chins of the two could be clearly palpated with the hands completely locked chin to chin. Under ether anesthesia an unsuccessful attempt was made to decompose the deadlock. No pulsation could be felt in the cord of the first fetus nor could any signs of life be detected. Fetal heart sounds of the second child were listened for but were not heard. The head of the first infant was readily severed by a stout pair of scissors. The head was now pushed up into the uterine cavity and the dependent cord was cut and tied. Ten minutes later the second infant emerged spontaneously. It showed no signs of life at birth. Neither child appeared the least macerated, and it was believed that both died during the labor. The first child weighed 4 pounds 2 ounces (1,871 Gm) and the second 4 pounds 13 ounces (2,184 Gm). Both were males. The decapitated head was expelled spontaneously and easily, and the placenta followed shortly after. One placenta was present with two cords and a single amniotic sac. A deep median episiotomy was done during the delivery and was repaired immediately after. Convalescence was as smooth as if nothing untoward had occurred. Healing was rapid and the patient was enjoying good health when last seen July 19, 1937.

From The Clinic.

COMMENT

The Index Catalogue from 1912 to 1932 lists only three titles of articles referring to collision or locking of twins, all in Swedish

Peters' case is the only one in recent years to be reported in the American obstetric literature

The commonest type is a breech followed by cephalic presentation, in a chin to chin locking

Peters' case emphasizes the value of careful observation aided by roentgenography and cesarean section when favorable circumstances present themselves

Our case presents the unfavorable or late stage of the complication in which decapitation of the first is usually the method of choice. The maternal convalescence was uncomplicated

Early and regular attendance at antepartum clinics is to be urged

Any patient in whom twins or any other peculiar presentation is suspected should have an antepartum roentgenogram. Any case in which there is a diagnosis of twins should be watched ceaselessly throughout labor

Cesarean section is the method of choice in delivery if the diagnosis of locking is made early while the infants are viable. If the diagnosis is not made until one or both infants are dead, decapitation or craniotomy is the method least dangerous to the mother

ACTINOMYCOTIC MENINGITIS WITH A PRIMARY FOCUS IN THE FINGER

REPORT OF A CASE DIAGNOSED DURING LIFE

D B MORRISON M D, TEKONSHA MICH
ARTHUR A HUMPHREY M D, AND JAMES E BAILEY M D
BATTLE CREEK MICH

Actinomycosis of the central nervous system is a rare disorder, although the first case on record was recognized only a few years following the first description of the organism sixty years ago. We have noted 110 cases in the literature. For an exhaustive historical survey and bibliography, the reader is referred to the work of Friedman and Levy¹ in 1936.

We feel that the case presented here is unusual because of the focus of infection, for in nearly all instances the primary site has been in the bones and cavities of the skull or in the lungs. It is also among the relatively few cases in which the diagnosis was made prior to death and in which the patient had not been recognized for some time as being the victim of this disease in a more or less chronic and disseminated fashion.

REPORT OF CASE

History.—A white boy, aged 12 years, admitted to the hospital Sept. 22, 1937, complained of pain in the occipital region, neck and back. These symptoms had been present for about three weeks prior to admission, with short remissions. Anorexia and vomiting had been present for ten days, and the patient had lost 15 pounds (68 Kg). Two weeks before entry the child was taken to the attending physician primarily because of a painless lesion on the terminal phalanx of the left index finger, which had been increasing in size. This resembled a felon. It was incised and through and through drainage established. A thick, brownish pus was obtained, and on admission the finger was still draining.

About eight weeks prior to admission to the hospital the patient accidentally punctured the finger with a sharp object while working in an onion field. Little note was taken of the injury at that time.

The child had always been thin and underweight. No history of any major illness was elicited.

Examination.—The patient was obviously poorly developed and undernourished and, though acutely ill, was well orientated and cooperative. The weight was 64 pounds (29.5 Kg).

There was nothing unusual about the skull, nose, ears and mouth. The pupils were equal and reacted, but there was a bilateral papilledema of the fundi. The neck was definitely rigid and there was pain on attempted flexion. The chest and abdomen appeared essentially normal. The left index finger showed small, unhealed incisions on either side of the terminal phalanx. A tumor the size of a walnut was noted in the left antecubital space. This was fixed to the surrounding tissue, and a similar one, somewhat smaller, was noted on the calf of the right leg. Neurologically, the reflexes were hyperactive. A bilateral Hoffman and a positive Kernig sign were present. The Babinski sign was not elicited.

On entry the patient had a temperature of 100.5 F, a pulse of 58, and a respiratory rate of 20 per minute. During the sixteen day period of observation the temperature varied between normal and 104 F. There were days when the patient appeared to be quite comfortable and actually seemed to be improving. Severe headache was a prominent symptom. Six days before death a spastic hemiplegia involving the right side of the neck, arm and leg developed. Diplopia and aphasia developed, followed by coma. Convulsions of the Jacksonian type occurred frequently during the last few days and were controlled only by intravenous administration of sodium amylal. The patient died following a convulsion on October 8.

The following laboratory procedures entered into the establishment of the diagnosis. On admission a spinal puncture revealed that the fluid was turbid and under pressure, 25 cc was removed. The following day this was repeated and the pressure was found to be 550 mm of water. The Queckenstedt sign was present. Several subsequent taps were performed, with a temporary relief of symptoms. Spinal fluid cell counts ranged from 2,676 per cubic millimeter on the first tap to 7,130 on the final one. Polymorphonuclear leukocytes constituted from 70 to 80 per cent of the cells, and the lymphocytes varied from 20 to 30 per cent. Globulin always occurred at least as a heavy trace, and a funnel shape pellicle formed in the fluid in a very short time. No organisms could be demonstrated, although repeated efforts were made. Various methods of taking cultures and a variety of mediums failed to grow any colonies. A rabbit inoculated intracranially showed no evidence of pathologic change when killed seven weeks later and examined post mortem.

September 24 material was taken for a biopsy from the wall of the tumor in the left antecubital space. This proved to be an abscess, and about 28 cc of a brown, purulent material was removed which seemed to penetrate into the deeper tissue. A cover-slip was placed over this fresh material and the microscopic examination showed a fungus with the typical rays and clubbed borders of Actinomyces. After this discovery similar yellowish clumps were found in the discharge from the initial lesion on the finger.

The blood count on admission showed a mild secondary anemia, and a leukocyte count of 23,700 per cubic millimeter. 88 per cent of which were polymorphonuclear leukocytes and 12 per cent lymphocytes. The urine was normal.

All reported cases of involvement of the central nervous system by Actinomyces have terminated fatally, nevertheless large doses of iodides were given. Spinal taps afforded only a transient relief.

Necropsy.—The left index finger presented the felon like lesion previously mentioned. The surgical incision in the medial portion of the left antecubital space also remained unhealed. The pus containing the actinomyces had been removed from this area fifteen days before death.

Nothing of note was observed in the abdomen or thorax except a small abscess the size of a walnut near the hilum of the right lung. The pus from this abscess was thick and yellow and fresh preparations demonstrated typical microbial elements.

The brain showed a marked flattening of the convoluted surface. The entire base of the brain and the upper portion of the spinal cord were covered with a thick yellowish purulent exudate. The fluid in the left ventricle and cisterna as well as

welling from the foramen magnum, was thick and purulent. The impression gained was that an abscess had ruptured into the left ventricle, but the involvement was so general and marked that this could not be proved. Wet, cover-slipped preparations showed numerous mycelial filaments in the thick fluid.

Microscopic examination was rather disappointing as far as the demonstration of the fungus was concerned. Sections through the brain revealed a dense lymphocytic exudate over the cortical surface in the involved areas. Aggregations of plasma cells and areas of hemorrhage were noted in the cortex immediately underlying this exudate. The sections through the wall of the ventricular abscess showed dense masses of plasma and lymphocytic cells, a marked intimal hyperplasia and areas of necrosis with vaguely formed mycotic filaments. Sections through the lung abscess and the antecubital abscess wall failed to demonstrate any typical actinomycetes.

COMMENT

The symptomatology of actinomycotic involvement of the central nervous system varies as to the type and extent of the pathologic process present. In an abscess the course may be long and associated with remarkable remissions, such a lesion may also mimic a neoplasm. In the meningitic form the outstanding characteristic is the comparative well being and excellent condition of the patient in contrast to the profound changes in the spinal fluid. The symptoms of a low grade meningitis are present, such as headache, vertigo and cervical rigidity. The patient is less toxic than in a tuberculous condition, and the spinal fluid changes differ. The latter condition is the most frequently confused, but here the spinal fluid is less purulent and the lymphocytes predominate in the differential count rather than the polymorphonuclear leukocytes, furthermore, the probability of isolating the specific bacillus is infinitely greater than finding the fungus.

Because of the indolent character of the lesion on the finger a fungous infection was suspected before the organisms were demonstrated in this primary focus and the antecubital abscess. The painless felon that did not improve after drainage could scarcely have been on the basis of a pyogenic infection.

An astonishing but typical feature of this case was the excellent physical and mental condition of the patient in the face of a spinal fluid tap, in which the purulent nature of the fluid almost prevented its removal through a large needle. This paradox was rendered even more bizarre by the apparent improvement from time to time with no variation in the cell count of the spinal fluid.

We were aware that many strains of this organism are apathogenic to animals and thus were not certain of producing the disease when it was injected into the rabbit. The failure to grow cultures from the spinal fluid, however, made us believe that the mycotic filaments do not stray far from the original focus in the fluid or lose their viability. It is interesting to note that organisms in the cerebral pus were of the branching, filamentous type, with only a vestige of clubbing and resembled that grown on artificial mediums. The pus from the antecubital abscess and finger, however, exhibited the typical clubbed "sulfur" granules.

If the lesions on the extremity had healed before the cerebral symptoms preempted the clinical picture, one would have been prone to consider this a "primary" actinomycotic involvement of the central nervous system. That such a primary site exists is questioned by Zeitlin and Lichtenstein² who in 1937 were able only by microscopic study to find an extracerebral primary lesion.

SUMMARY

The case of basilar actinomycotic meningitis here reported was diagnosed prior to death. The point of entrance through the wound on the finger is unusual, the primary focus in most cases being in the cranial bones or the respiratory system.

It is felt that diagnosis by means of demonstrating the organism in the spinal fluid is difficult, but in any case of purulent meningitis in which the patient is not acutely ill, actinomycetes may be suggestive as a causative factor.

NOISE AND ITS EFFECT ON
HUMAN BEINGSNOISE CONTROL AS A BY-PRODUCT OF
AIR CONDITIONINGCAREY P. McCORD, M.D.
DETROITEDWIN E. TEAL, M.S.
ANN ARBOR, MICH.AND
WILLIAM N. WITHERIDGE, M.S.
DETROIT

Air conditioning and noise prevention have a definite relationship in controlled human environments. Whenever the windows of buildings are kept closed to exclude noise, air conditioning may become a practical necessity. Conversely, it follows as a natural consequence that occupants of buildings living in artificial atmospheres and thus not dependent on open windows and doors will in some measure be protected against extraneous noises arising from traffic, nearby buildings or low flying aircraft. This beneficent by-product of air conditioning is considered of such importance by the Association's Committee on Air Conditioning that this report has been prepared to embody present concepts of noise in its relation to the comfort and health of human beings.

The multiple and insidious ill effects of noise constitute an inadequately recognized baneful influence on the lives of many million persons throughout the country, especially those who live in urban areas. In noisy industrial employments it is not unusual to find in those groups of workers below 30 years of age as many as 50 per cent with some degree of impaired hearing. This noise deafness constitutes the most serious and tangible of the ill noise effects (echeoses), but there is, in addition, a host of scarcely measurable injuries made evident by neuroses, loss of sleep, excessive fatigue, emotional disturbances and the like that jeopardize the complete well-being of most persons, and in which noise may well play a part.

DEFINITIONS

Before the effects of noise on human beings are discussed a few of the more frequently used technical terms will be defined.

1. *Sound*—In a physical sense, sound may be defined as a wave motion or vibration in an elastic material medium such as the atmosphere. Physiologically, sound is the sensation produced primarily by air-borne vibrations reaching the ear. The auditory nerve impulses which are perceived as sound originate in the cochlea, a specialized part of the inner ear. This organ is sensitive to displacements of the surrounding fluid (endolymph) which correspond to the variations in air pressure commonly termed "sound waves."¹ Bone

conduction of sound vibrations also occurs to some degree and is made use of in certain types of "deaf aids" Bone conduction is particularly important when noise is simultaneously transmitted by sound waves through the air and by vibrations through the skeleton

2 *Noise*—Noise is sound which is generally considered unmusical, confused discordant, irksome or disturbing. Physically, noise may be the result of either a single frequency or many component frequencies

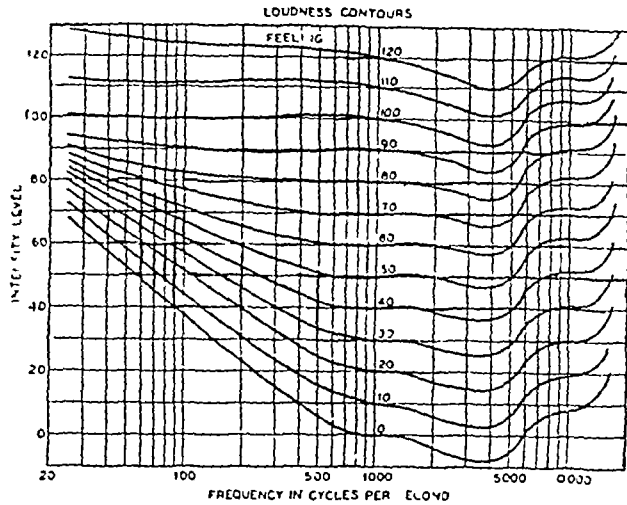

Fig 1—Relation between subjective loudness sound intensity and sound frequency (Proposed Standards for Noise Measurement as adopted June 26 1933 by the A S A Committee on Acoustical Measurements and Terminology Journal of the Acoustical Society of America 5 109 [Oct] 1933)

which bear no harmonic relation to one another. Harmonic sounds also may have the same unpleasant effect as noise if their intensities become too great. It should be borne in mind that the distinction between noise and music cannot be made on a strictly physical basis, since individuals differ widely in sensitivity, temperament and sound appreciation and therefore will not unanimously agree to an arbitrary differentiation between musical sounds and noise

3 *Intensity and Loudness*—Besides frequency or pitch (number of vibrations or cycles per second) sounds have two closely related attributes—intensity and loudness. That intensity and loudness are not synonymous is due to the fact that the ear is not uniformly sensitive throughout the entire range of audible frequencies. 'Intensity' is a physical term used to denote the amount of sound energy passing through a unit area per unit of time. 'Loudness,' on the other hand, refers to the sensation evoked by a given sound intensity. Thus the loudness of a sound depends both on its intensity and on the physical characteristics of the ear. The ear is sensitive to a range of frequencies from 16 to 22,000 cycles per second but is most sensitive between 1,000 and 5,000 cycles (fig 1)

4 *Decibel Scale*—Because of the enormous range of intensities experienced with audible sounds, a logarithmic scale is much more convenient than an arithmetic scale for the measurement or comparison of sound intensities. The unit of the logarithmic scale in general use is the bel and is defined thus: If the intensity of a sound increases ten times, its intensity level is said to have risen one bel; if it increases a hundred times, two bels. Accordingly, the rise in bels is simply the common

logarithm of the ratio of the two sound intensities. The "decibel" or one tenth of a bel, is a more convenient unit for sound intensity measurements and as a result is used in preference to the bel.

The smallest intensity of sound required to produce a sensation is said to be on the threshold of audibility, or threshold of hearing. This point is zero on the decibel scale (tables 1 and 2). When the intensity of sound is increased until it is felt as well as heard, it is said to be on the threshold of feeling. This point, known as the upper limit of audibility, is near 120 decibels for certain sound frequencies. At such a level sound has an intensity of one trillion (1,000,000,000,000) times its threshold value. A change of five decibels is barely perceptible at very low noise levels, whereas a change of about 0.3 decibel is noticeable at noise levels of 80 decibels or higher.

COMBINED SOUNDS

If one loud noise is present with several lesser noises the total noise level in decibels usually is but little above that of the loudest noise. Consequently the amount of reduction that may be obtained in the total noise level will correspond closely to the reduction that can be made in the loudest component. If several noises arrive at one point with the same intensity, the combined noise level will be only a few decibels above that of any one component.

For example, two identical whistles sounded together do not make a noise twice as loud as one. Instead they make a combined sound three decibels louder than that of one whistle. Thus if each whistle produces a 75 decibel sound, the two together will give a sound of 78 decibels. It would take 100 identical whistles to make a noise 20 decibels louder than that of one whistle sounded alone (table 3).

MEASUREMENT OF NOISE

1 *Sound Level Meter*—Accurate measurements of the intensity of sound are made with "sound level meters" in which acoustical oscillations are translated into electrical oscillations and then amplified by high quality vacuum tubes. Measurements which largely depend on the ear cannot be considered accurate and may lead to discrepancies which prevent direct comparison between the results of independent noise studies.

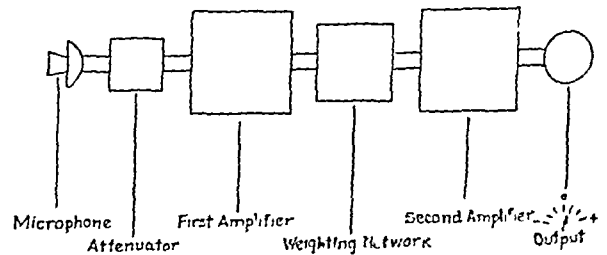

Fig 2—Diagram of sound level meter

Figure 2 is a block diagram of the typical sound level meter. The "weighting network" of this meter is designed to simulate the ear's reduced sensitivity at the highest and lowest frequencies (fig 1). Whenever it is desired to analyze the character of a sound the weighting network is replaced by an analyzing circuit using filters which cut out all but certain bands of frequencies. The sound level meter then becomes an

analyzer by which sounds of particular frequency may be identified from complex noises, this is especially valuable in determining the source of noises from machinery

2 *Audiometer*—Another instrument for the measurement of noise is the “audiometer,” which may be used over almost the entire auditory spectrum either

are made with the other two tuning forks in order to determine the approximate frequency distribution of the noise, as well as the intensity at each frequency

EFFECTS OF NOISE

There is both practical and experimental evidence that noise has been responsible for impaired hearing, fatigue, neuroses, increased blood pressure, and decreased working and mental efficiencies. Experience indicates that a noise level of 90 decibels or higher is definitely harmful to the human ear.⁵ Exposure to prolonged noises of lower level, which is the case with many occupational noises, is also harmful, but the extent of harm done is not well known and cannot be fairly estimated at this time.

1 *Animal Experiments*—Blake⁶ states that experiments on animals show very definitely that high-pitched sounds of various kinds and low-pitched sounds under certain conditions of resonance produce degenerative changes in the organ of Corti, “beginning in the nucleated ciliated cells, progressing to the neuron and then, secondarily, attacking the vibrating mechanism and extending to the contiguous membranous labyrinth.” A few experiments with animals have shown a tendency for hearing to be impaired more by vibrations transmitted through the bony structure of the body to the ear than by air-borne vibrations coming through the external ear.

Popoff⁷ placed white mice in a factory where hot steel bars were hammered into scythes. The principal sound frequencies present were from 60 to 100 cycles and from 2,000 to 3,000 cycles per second. One group of ten mice was placed in a cage in contact with the

TABLE 1—Relation of Certain Sounds to the Threshold of Hearing*

| Average Decibels | Source or Description of Sound |
|------------------|--|
| 130 | Threshold of painful sounds; limit of ear's endurance |
| 120 | Threshold of feeling (varies with frequency) |
| 115 | Airplane motor (1 600 revolutions per minute) 18 feet from propeller |

G., King, A. J., and Davies, H., The Measurement of Noise with Special Reference to Engineering Noise Problems, J. Inst. Elect. Engineers 75: 401 [Oct.] 1934; Winton and Bayliss^{1a}; Kaye^{2b}; Geiger³; American Society of Heating and Ventilating Engineers Guide for 1936).

for measurement of hearing deficiency or for determining the masking effect of a noise. This instrument consists of a unit for generating, in a special earphone, a standard sound, which may be adjusted to any given level of sound intensity. To determine the masking effect of a noise, the intensity of the standard sound in the earphone is varied until it can just be heard in the presence of the outside noise. For hearing measurements, the signal from the audiometer is varied over the audible range of frequencies to determine the threshold of perception of the subject at several sound frequencies.

3 *Tuning Fork Method*—A simple method of measuring the masking effect of noise sufficiently accurate for some types of field work employs only three tuning forks producing different sound frequencies (usually 128, 512 and 2,048 cycles per second) and a stop watch.⁴ The observer, in the presence of the noise to be measured, strikes one of the tuning forks a “standard” blow. At the same instant he starts the stop watch. The fork is then held near the ear and moved back and forth slightly until its tone is completely masked by the noise, at which time the watch is stopped. The average time for several tests is subtracted from the time during which that particular tuning fork remains audible in a quiet place. This difference is then translated mathematically into decibels. Similar measurements

4 American Society of Heating and Ventilating Engineers Guide for 1936.

vibrations for eight hours each day. In twenty days an examination of one of the mice from the cage on the floor showed destructive changes at the commencement of the basilar membrane. The corresponding sections of the organ of Corti were destroyed and changes were noted in the neighboring ganglion cells. In three months the destruction was observed in another mouse to have extended to higher windings of the cochlea. There was destruction of the ganglion cells with their afferent and efferent fibers inside the lamina spiralis and corresponding portion of the modiolus. In eight months, ganglion cells and nerve fibers of the upper convolutions had disappeared. At the same intervals, mice from the suspended cage were observed to have suffered no changes in their auditory apparatus.

Wittmaack⁸ subjected six guinea pigs to the continuous ringing of an electric bell suspended in their cage, dissection at five, ten, twenty, thirty, forty and sixty days showed no damage to the auditory apparatus. When the vibrations were transmitted through the tin floor of the cage, the animals became emaciated rapidly and two died after fourteen days. The others were killed and characteristic degeneration was found in the cochlea.

TABLE 3—The Change in Decibels Corresponding to Multiple Increases in Sound Intensity

| 1 000 | 30.0 |

Although these experiments tend to indicate that bone conduction is the more active cause of ear degeneration, the work of other investigators indicates that air conduction likewise is responsible for deafness and deterioration of the auditory apparatus. Yoshii,⁹ repeating Wittmaack's experiments with guinea pigs, was able to demonstrate the presence of lesions after exposure of the animals to purely air-conducted sounds. Von Eichen⁸ plugged the left ear of an animal and subjected it to a whistle tone C5.¹⁰ On examination, he found that only the right labyrinth was affected. Grunenberg⁶ exposed the right ear of a pigeon for about fourteen days to continuous tones of whistles A3 and A4.¹¹ and found that damage occurred only in the right cochlea. Hoessli⁶ placed animals in a suspended section of an iron water pipe which was struck continuously by an automatic hammer to create sounds similar to those produced in boilermaking. He found that when one ear was closed a degenerative process occurred only in the other ear and that when both ears were closed there was apparently no damage done to either ear. Hoessli⁶ also conducted experiments with animals insulted, as far as bone conduction was concerned, by a matting of felt placed on the floor of the cage, as suggested by Wittmaack, but found that this had no effect in preventing the onset of the disease process.

Boulin¹² reported that mice subjected to noise did not thrive as well as those kept in a quiet place.

With the cathode ray oscillograph, Wever and Bray have studied electrical changes in the auditory nerve of anesthetized animals in response to sound. "When exposed to tones sufficiently loud to make them deaf to the tones, dogs were found to lose the electrical cochlear response to the tones. The electrical response for high tones is more readily picked up from the base of the cochlea than it is from the apex, while the reverse is true for low tones."¹³

Davis¹⁴ subjected cats and guinea pigs to tones of from 600 to 2,500 cycles per second varying in intensity from 65 to 106 decibels. Four animals exposed to a 600 cycle tone at 95 decibels for seventy days showed a maximum loss of sensitivity of 20 decibels. Three guinea pigs exposed to a 2,400 cycle tone at 97 decibels for 40 days and four exposed to a 2,500 cycle tone at 106 decibels for forty-five days all showed loss of sensitivity electrically and degeneration of the organ of Corti histologically. The loss of sensitivity in this group varied from 20 to 76 decibels.

Microscopic examination of animals subjected to definite sound frequencies has shown that the section of the cochlea most seriously affected is that which is believed to be resonant to the test frequency.

In guinea pigs and other small mammals subjected to such stimulation, injury to the apical turn of the cochlea in response to low tone stimuli, and basal disorganization for high tones has been demonstrated histologically. More recently despite the very considerable histological difficulties which arise when dealing with human material, lesions in the basal turn have been demonstrated in boilermakers and others, whose working conditions are such that they are subjected to loud noises of high frequency for some years. Such men become deaf to high tones by correlating the range of frequencies over which the patient was deaf with the position of the cochlear injury examined histologically after death, those regions of the human basilar membrane which are resonant to frequencies from 2,000 cycles per second upwards have been roughly located.¹⁵

2 Human Hearing Impairment—Audiometer experiments on human beings indicate that workmen exposed to particular frequencies after a time become deaf to those frequencies, and in many cases deficiency appears first in the high frequency range. The lower part of the organ of Corti, which is the area concerned with the perception of the higher frequencies of sound,¹⁶ appears to be especially vulnerable, either because of the small amount of blood supply to that area (Haber mann) or because it is the most delicate and highly developed part of the organ (Rodger).¹⁷

The study of industrial noises is of comparatively recent date, and the increasing interest is accounted for partly by the increase in industrial noises and partly by a better realization of their harmful effects and of the waste of energy which they produce.

Auditory diseases arising from occupation generally are due to a chronic degeneration of the cochlea. They are serious in proportion to the length of time employees have worked at noisy occupations.¹⁸ Occupational

¹¹ 427 and 833 cycles respectively.

deafness usually develops in the worker gradually, but in many cases of exposure to intense high frequencies the accrued damage is permanent

Gottstein and Kayser found that of seventy-five smiths and machinists 40 per cent were definitely hard of hearing and only 39 per cent had normal hearing. Holt found only 10 per cent of forty coppersmiths with normal hearing. Barr reported normal hearing in only 9 per cent of 100 boilermakers. Habermann found that of thirty-one boilermakers none had normal hearing.¹⁷

In a survey reported by the New York Department of Labor¹⁸ 1,040 workers in many different noisy industries were tested for deafness and, as might be expected, the highest incidence of deafness for any age group was found in the noisiest industries, that is, where the noise level was between 60 and 80 decibels. Of those workers who were exposed to noise for twenty-five years or more and who did not have a history of disease which might have been a causative factor 26.9 per cent were deaf in some form, while in the group exposed to noise for less than one year only 6 per cent appeared to have any impairment of hearing. Of the 246 persons found deaf, ninety-one had histories of infectious ear involvement and the deafness of 155 was traceable to industrial causes.

McKelvie¹⁹ found a 24.3 per cent occurrence of deafness among 1,011 weavers examined, of which 67 per cent was nerve deafness. However, no case of nerve deafness, which is the type due to long exposure to noise, was found in weavers employed less than ten years. The number of cases increased with the years of employment, and this was especially evident among those who had worked twenty years or more.

It has been observed that many locomotive crewmen are partially deaf, and if this deafness has progressed too far they are apt to be turned down after years of continuous work when they come up for annual examination.²⁰ Thompson²¹ has stated that 45 per cent of these workers have impaired hearing. Gilbert⁸ noted that 58 per cent are affected within five years, and after twenty years 52.1 per cent have defective hearing. Peyser⁹ believed that most of this deafness among locomotive workers is due to bone conducted vibrations. McCord²² reported a 52 per cent incidence of occupational deafness in train dispatchers, and this occurs largely in the telephone ear—the left.

Very loud, sudden noises, explosions or excessive pressure changes are dangerous, particularly to the tympanic membrane or the bony structure of the middle ear. In a trade such as drop forging where large pressure changes occur, it is found that many workmen acquire a thickening of the eardrum which prevents airborne sounds from passing readily to the inner ear. So regularly are drop forge operators partially deaf that this impairment in some instances is regarded as their proof of occupational experience. Unless hearing is damaged, applicants claiming experience may not be employed.

Seventy-five soldiers who handled and fired antiaircraft guns were examined before firing was begun and reexamined one week after completion of the firing

tests, which occupied a period of about two months. Vadala²³ concluded from these tests that "the long continued and oft repeated tubotympanic congestion resulting from gunfire has a gradual diminishing effect on the acuteness of hearing by causing a chronic catarrhal condition of the tympanum with loss of elasticity of the drum, and fibrous adhesions."

Noisy work performed in a confined space is more harmful to the ears than if done in the open air. Hammering inside a boiler or firing in an enclosed rifle range is especially dangerous since resonance, reflection and reverberation accentuate the noise. On this account work in much used vehicular or railway tunnels or subways is conducive to loss of hearing.

It is pointed out in the New York report on "City Noise" that policemen and taxi drivers are very often affected with deafness because of their continuous work in traffic. One British physician has expressed the belief that the opening of a new street carrying heavy traffic through a certain formerly quiet suburb caused the number of illnesses in that community to increase.

It has been observed that dizziness sometimes is a result of exposure to excessive noise or vibration.²⁴ Sounds that are of such pitch or intensity as to cause a tingling sensation or pain in the ear will probably cause permanent damage if exposure is continued over a long period.

High-pitched tones appear to be more dangerous than tones of low pitch from evidence both in human experience and in animal experimentation. The din in boiler works is considered by some investigators to be more injurious than the roaring in cotton spinning mills, the report of small caliber artillery and machine guns is likewise more injurious than the boom of heavy guns, unless the latter actually ruptures the tympanic membrane.

3 Effect of Noise on Working Efficiency—Most of the investigative work on noise has been concerned with the physiologic effects of a noisy environment on non-auditory performance. This is practically justifiable since relatively few tasks of daily life have a direct, and fewer still an exhaustive, auditory basis. Just how much and in what manner the initial effects of a noise stimulus on nonauditory performance differ from the final or chronic effects is a problem offering extensive opportunity for research.

Weston and Adams²⁵ observed that weavers using ear defenders in alternate weeks over a period of twenty-six weeks had an increased output of about 1 per cent when the defenders were worn. In this case the effect of ear defenders was to reduce the loom noise from 96 to 87 decibels. Their experiments prompted the conclusion that, "even after years of work in a noisy environment, the worker does not become completely adapted or acclimated to noise but goes through the process of adaptation daily." In a later series of experiments they²⁶ found that the output of weavers was increased about 3 per cent by an apparent decrease in noise level of 15 decibels (from 96 to 81) when ear

defenders were used. In terms of personal efficiency, this was equivalent to an increase of about 75 per cent with subdued noise. It was stated that the change from 96 to 81 decibels probably represented about a 50 per cent reduction in apparent loudness.

Table 4 gives the effect on the sensation of loudness by reducing sound intensity 10 decibels at different positions on the decibel scale. Although the results of independent investigations do not agree in every instance, it is apparent that the initial sound intensity as well as the change in intensity must be considered when estimating the effect of such a change on the sensation of loudness.

Obata²⁸ ran tests on children and adults for their efficiency in addition and in marking out certain Japanese letters (syllables) in a confused jumble of 1,600 letters under the influence of various types of noise and music. In nearly every case, working speed rather than accuracy was reduced. Soft recorded music appeared to have a more distracting effect on the subjects than did ordinary low level noise. However, if

Data for this study were gathered before and after the offices were quieted. The noise level was reduced 14.5 per cent and the average efficiency of workers was increased 8.8 per cent. Errors of typists were reduced 29 per cent, while those of machine operators were reduced 52 per cent. Employee turnover decreased 47 per cent and absenteeism dropped 37.5 per cent.

Dennis,³¹ reporting the results of the 1930 New York noise survey, gives the following information: A 12 per cent increase in output of office workers followed a reduction of the noise level from 45 to 35 decibels. A 42 per cent reduction in errors in the telephone room of a telegraph company, with a 3 per cent drop in cost, was effected by a reduction of the noise level from 50 to 35 decibels. Boulin³² states that a reduction from 55 to 43 decibels was beneficial to typists but that further reduction showed no advantage. Laird³³ reported in the results of a metabolism experiment at Colgate University that 19 per cent less energy was consumed by typists after noise of about 50 decibels in the experimental room was reduced to 40 decibels (from 50 to 60 per cent reduction in loudness) by the addition of sound absorbing wall panels. Letters were typed 43 per cent faster during the "quieted phase" of the experiment. Laird also has found that accuracy in immediate memory for nonsense syllables was increased 15 per cent, and delayed memory increased 8 per cent by reducing a complex noise from 50 to 40 decibels.³¹

Luckiesh,³³ in an experiment with nine subjects performing a standard visual test under constant illumination, first in a quiet and subsequently in a noisy room, has found that noise increases the time required for the performance of the test by approximately 6 per cent and suggests that an even greater effect might be observed if the experiment was conducted in a factory where the noises were of a nonrhythmic character. As early as 1893, Wundt³⁴ showed that reaction times may be retarded by noise, both with auditory and with visual signals.

4 Effect of Noise on Intracranial Pressure.—In 1930 Kennedy conducted investigations at Bellevue Hospital in New York to determine the effect of noise on intracranial pressure. Using as his subjects persons who had previously had sections of their skull removed in the treatment of tumors or injuries but were otherwise normal, he was able to produce graphic records of the increased brain pressure occasioned by certain noises. The recording device consisted of a drum containing a partial vacuum placed over the soft or thin section of the skull. A sensitive mechanism transmitted the pressure variations within the cranium to a carbon black recording cylinder. "A sharp loud report produced notable irregular disturbance and a rise in intracranial pressure to four times normal. A second noise caused a second peak in the curve."³⁵ The sudden noises used in these experiments caused increased pulse rates, increased blood pressure and irregularities in heart rhythm. Landis has shown that the noise of a firecracker produced an increase in the systolic blood pressure of 20 mm in twenty seconds.³¹

TABLE 4—Effect of Reducing Sound Intensity Ten Units at Different Positions on the Decibel Scale

| Sound intensity in Decibels | | Per Cent Reduction in Sensation of Loudness* | | |

‡ Interpolated.

the test period was long enough to produce fatigue, the subjects apparently obtained some relief from music whereas noise enhanced the fatigue with consequent adverse effect on efficiency.

Pollock and Bartlett²⁵ found that discontinuous loud mechanical noise was more disturbing than continuous noise of the same type, disturbance was not simply a function of loudness, for "soft" phonograph recordings proved almost as distracting, especially if the subject matter reproduced was "interesting." These investigators concluded that "noise in general tends to produce slight and readily recoverable diminution of efficiency."

In a German factory where experienced workers assembled temperature regulators, sixty imperfections were found in a group of eighty regulators. The assembly room was next to a boiler shop. When this work was performed in a quiet place, 110 units were assembled in the same time previously required for eighty units and only seven imperfections were found. In a packing room equipped with a noisy ventilating fan, output was increased 12 per cent when the fan was turned off, in spite of the poorer ventilation which existed during that period.²⁹

5 Effect of Noise on Digestion—That noise may seriously affect the normal digestive functions and thus assume a causative role in so-called nervous indigestion is indicated by several lines of evidence. Observations on human beings by Smith and Laird³⁶ at Colgate University showed that a noise of 60 decibels or above inhibited the normal peristaltic activity of the stomach. A noise of from 80 to 90 decibels caused a decrease of 37 per cent in the number of stomach contractions per minute. Laird³⁷ found that a noise intensity of 60 decibels or more cut down the secretion of saliva by about 44 per cent and reduced the flow of gastric juices, however, a noise level of 40 decibels reduced the saliva flow only 17 per cent and had no effect on the flow of gastric juices.

6 Fatigue Due to Noise—If work must be done in the presence of a distracting noise, one's nervous system probably makes a continuous effort to adapt itself to that disturbance. A more intense mental application is required to focus attention on certain types of work, and eventually nervous or mental fatigue may occur.

The intensity and pitch of noise most likely to produce nervous fatigue is difficult to determine because of individual differences. Even for one individual the limits vary from day to day because sensitivity to noise depends, among other things, on health, muscular fatigue and mental attitude. It has been observed that noise of 50 or more decibels is generally annoying and productive of irritability. Sounds are more apt to be fatiguing if their frequencies are either above or below the range of frequencies normally used for speech.³⁸ The frequencies of most speech sounds lie between 200 and 6,000 cycles. It appears that pitch or frequency of sound is as important as intensity of sound as a factor in producing mental fatigue.³⁹ In fact, from the results of experiments at Colgate University on the "annoyance effect" of noise it has been suggested that "a noise of low frequency and high intensity may be less annoying than a high frequency noise of low intensity."⁴⁰

Long continued exposure to annoying or fatiguing sounds may soon lead to a neurasthenic or psychasthenic state. The nervous system has been found to be of a rhythmic nature and as a result it responds more readily to rhythmic than to irregular stimuli. Even though adaptation to a regular or rhythmic sound is possible to the extent that one becomes unaware of that sound, nervous energy is expended in such a process, and it may be expected that long exposure will gradually bring on fatigue. Continuous exposure to irritating noises may lower one's threshold of feeling and thus produce hypersensitivity to noise.

Relaxation in quiet surroundings after working hours may be an important means of preventing chronic ear diseases and fatigue due to noise. As pointed out by the New York Noise Abatement Commission in its report entitled "City Noise," sleepless nights are many times the result of unnecessary or thoughtlessly produced noises. Archambault,⁴¹ commenting on the treat-

ment of insomnia in persons obliged to dwell in congested tenement districts, makes the following statement: "I do not hesitate to prescribe [for these patients] some of the milder sedatives and hypnotics in order to facilitate or procure sleep, being morally convinced that the judicious use of such medication is infinitely less detrimental than the persistent insomnia which exhausts both physical energy and moral stamina."

McKenzie states that "while noise does not induce organic disease, apart from deafness, it does induce a condition of functional weakness or disability, which is manifested in exhaustion more or less severe according to (1) the kind of noise, (2) the normal mental and constitutional makeup of the recipient and (3) the state of health at the time of his exposure. And this state of fatigue, though itself not a disease, opens the door to disease."⁴²

PREVENTION OF NOISE

Since the ear does not have an external protector similar to the lid that guards the eye against disagreeable stimuli, it is desirable to reduce or eliminate unpleasant and harmful noises through whatever means may prove possible. When air conditioning appliances lead to the closure of windows and doors and at times introduce double windows and doors, extraneous noises may be reduced from 5 to 30 decibels with an average near 10. Depending on the loudness of extraneous noises, these barriers may operate to protect the occupants of air conditioned spaces against as much as 75 per cent of noise, but more often in the general range from 45 to 55 per cent.

In view of the array of evidence earlier presented in this paper tending to establish the harmful effects of noise, it at once becomes apparent that air conditioning apart from any values related to the quality of the air in occupied areas, serves a helpful purpose through interposing barriers against noises of outside origin. The statements just made fulfil the chief purpose of this publication. However, since the scope of this paper embraces a general discussion of noise, casual comment is now made on other aspects of the elimination and avoidance of noise.

In addition to the functions served by air conditioning as a noise abater, the eradication or reduction of noise may be accomplished through measures falling into three general categories: (1) elimination of noise at its source, (2) reduction of noise by altering the surroundings and (3) personal protection against noise.

1 Elimination of Noise at Its Source—Much noise is unnecessarily produced by the needless sounding of automobile horns, the operation of loud radios, the harboring of noisy animals, and so on. Manifestly, this type of noise can be eliminated only through regulatory and educative procedures. Referring now to noises of more nearly pardonable character, such as those in industry, it is maintained that elimination at the source is the most satisfactory method, although it may be expensive and difficult, requiring special mutual experimentation and innovation. However, over a period of several years, the cost of this method may be less than either of the other two procedures. The noise in machinery is often the result of faulty design and worn parts, redesign or repair of such equipment may result in greater life, less loss of power and consequently lower operating cost. Silent operation may be accomplished by the use of well balanced parts to

⁴² McKenzie Dan. Noise and Health. *Brit. M. J.* 2: 636 (Oct. 6) 1934.

reduce the tendency to vibration, by keeping the machinery well lubricated by isolation of machinery in sound proof rooms, and by the use of flexible cushioning supports

As an example, to avoid the noise and vibration of a pneumatic riveter, pressure riveting may be substituted for impact riveting, the automobile industry has successfully applied pressure riveting to the assembly of certain units of steel bodies and frames. Another solution is the use of welding in place of riveting, and at the present time the steel skeletons of many buildings and other structures are welded instead of riveted.

2 Reduction of Noise by Altering the Surroundings—Distinct from the noise lessening effects of air conditioning noise entering occupied areas from extraneous sources may in some measure be controlled through the use of sound absorptive material in or on walls, ceilings and floors. Ordinarily the reduction of the noise level by these measures is on the order of 5 to 10 decibels, which, depending on the character of the noise otherwise present, may mean a reduction in the general range of from 30 to 50 per cent. Radio broadcasting studios have found it possible and practical to eliminate as much as 80 per cent of both interior and exterior noise. Many modern offices are made noisy by the use of endless typewriting, duplicating, accounting and addressing machines, along with the general din of conversation. The elimination of such noise should be controlled at the source through the use of "silent" or noiseless office equipment. That which cannot be so eliminated may be minimized through proper architectural devices.⁴³

3 Personal Protection Against Noise—Many writers have described methods of personal protection against noise and vibration, as, for example, the use of wax, petroleum impregnated cotton, or soft rubber ear defenders against air-conducted noise, and the wearing of soft soled shoes for protection against floor or ground vibrations which might be transmitted through the bony structure of the body. Protection further may be promoted by the use of straw, felt or rubber mats, and special chairs or platforms mounted on springs. In hammering operations, the use of benches with springs for supporting the work does much to reduce the vibrations experienced by the workman at each blow. Faithful wearing of ear plugs undoubtedly serves some purpose in protecting against air-borne vibrations, but in some instances aural dermatitis may be produced by these appliances. Naturally, such devices serve no useful purpose in protecting against bone-conducted vibration by which there is some proof that greater damage may be produced.

COMMENT AND SUMMARY

This committee recognizes that proper air conditioning is one factor tending to diminish the ill effects of noise of some types. The procurement of closed windows, doors and other sound barriers commonly associated with artificial climates in public buildings, office buildings, department stores, theaters and so on may eliminate as much as 75 per cent of the noises of extraneous origin.

In industry, air conditioning offers little promise of protection against noise for workers employed near

the origin of noise. Vibration in ranges below audibility has a prominent role in the production of injuries arbitrarily classed as noise diseases. Although inaudible vibrations may involve occupied areas that may be air conditioned, obviously no protection can be secured from such vibrations by air conditioning.

The compilation of material making up this report presents extensive evidence that genuine injury is wide spread as a result of noise action and that noise deafness is the chief of these dysfunctions in terms of both frequency and severity.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED
FRANKLIN C. BING, SECRETARY

GLORY WHEAT BREAKFAST CEREAL

Manufacturer—The Teichgraber Milling Company, Gypsum, Kan.

Description—Wheat cereal product containing the embryo and a considerable amount of the bran.

Manufacture—Selected winter wheat is cleaned, scoured, tempered with 3 per cent of water for twelve hours and milled. The breakfast cereal is obtained by selection of the most uniform granulation "germ middlings." Care is used to keep the product uniform in bran particles. The cereal is heat treated for fifteen minutes at 77° C. to destroy insect infestation, screened and automatically packaged and weighed.

Analysis (submitted by manufacturer)—Moisture 10.8%, total solids 89.2%, ash 1.4%, fat (ether extract) 2.3%, protein (N × 5.7) 14.0%, crude fiber 1.2%, carbohydrates other than crude fiber (by difference) 70.3%.

Calories—3.58 per gram, 102 per ounce.

MORNING DEW BRAND CORN MEAL MUSH

Manufacturer—Streator Canning Company, Streator, Ill.

Description—Canned mush made from whole kernel yellow corn, degerminated yellow corn meal, salt and water.

Manufacture—The ground yellow corn, degerminated yellow corn meal, water and salt are mixed and heated to 82° C. by live steam. The mush is mechanically filled into cans, which are sealed and processed at 121° C. for eighty-two minutes.

Analysis (submitted by manufacturer)—Moisture 83.6%, total solids 16.3%, ash 0.7%, fat (ether extract) 0.1%, protein (N × 6.24) 1.8%, crude fiber 0.4%, carbohydrates other than crude fiber (by difference) 13.4%.

Calories—0.62 per gram, 18 per ounce.

- (1) DOVE BRAND EVAPORATED MILK
- (2) GEHL'S BRAND EVAPORATED MILK
- (3) PURITY BRAND EVAPORATED MILK

Manufacturer—Badger Milk Products Company, Milwaukee, also known as Gehl's Guernsey Farms, Inc.

Description—Unsweetened sterilized evaporated milk.

Manufacture—Milk from company and government inspected farms is tested, preheated, evaporated under vacuum, homogenized, cooled, standardized to meet government requirements for butter fat and total solids, filled into cans, sealed and sterilized.

Analysis (submitted by manufacturer)—Moisture 74.3%, total solids 25.7%, ash 1.7%, fat (ether extract) 7.6%, protein (N × 6.38) 6.6%, lactose (by difference) 9.6%.

Calories—1.4 per gram, 40 per ounce.

THE SAN FRANCISCO SESSION

AMERICAN MEDICAL ASSOCIATION, EIGHTY NINTH ANNUAL SESSION
SAN FRANCISCO, CALIF., JUNE 13 17, 1938

OFFICIAL CALL

TO THE OFFICERS, FELLOWS AND MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

The eighty-ninth annual session of the American Medical Association will be held in San Francisco, June 13-17, 1938

The House of Delegates will convene at 10 a. m., Monday, June 13. In the House the representation of the various constituent associations for 1938, 1939 and 1940 is as follows:

| | | | |
|----------------------|---|---------------------|----|
| Alabama | 2 | New Hampshire | 1 |
| Arizona | 1 | New Jersey | 4 |
| Arkansas | 2 | New Mexico | 1 |
| California | 7 | New York | 19 |
| Colorado | 2 | North Carolina | 2 |
| Connecticut | 2 | North Dakota | 1 |
| Delaware | 1 | Ohio | 1 |
| District of Columbia | 1 | Oklahoma | 2 |
| Florida | 2 | Oregon | 1 |
| Georgia | 3 | Pennsylvania | 11 |
| Idaho | 1 | Rhode Island | 1 |
| Illinois | 9 | South Carolina | 2 |
| Indiana | 4 | South Dakota | 1 |
| Iowa | 2 | Tennessee | 6 |
| Kansas | 3 | Texas | 1 |
| Kentucky | 3 | Utah | 1 |
| Louisiana | 2 | Vermont | 1 |
| Maine | 1 | Virginia | 3 |
| Maryland | 2 | Washington | 2 |
| Massachusetts | 7 | West Virginia | 2 |
| Michigan | 5 | Wisconsin | 3 |
| Minnesota | 3 | Wyoming | 1 |
| Mississippi | 2 | Alaska | 1 |
| Missouri | 4 | Hawaii | 1 |
| Montana | 1 | Isthmian Canal Zone | 1 |
| Nebraska | 2 | Philippine Islands | 2 |
| Nevada | 1 | Puerto Rico | 1 |

The fifteen scientific sections of the American Medical Association, the Medical Corps of the Army, the Medical Corps of the Navy and the Public Health Service are entitled to one delegate each.

The Scientific Assembly of the Association will open with the general meeting to be held at 8 p. m., Tuesday, June 14. The sections will meet Wednesday, Thursday and Friday, June 15, 16 and 17, as follows:

| CONVENING AT 9 A. M. THE SECTIONS ON | |
|--------------------------------------|----------------------------------|
| Surgery, General and Abdominal | Nervous and Mental Diseases |
| Ophthalmology | Dermatology and Syphilology |
| Pediatrics | Gastro-Enterology and Proctology |
| Pharmacology and Therapeutics | Radiology |
| CONVENING AT 2 P. M. THE SECTIONS ON | |
| Practice of Medicine | Pathology and Physiology |
| Obstetrics and Gynecology | Preventive and Industrial |
| Laryngology, Otology and Rhinology | Medicine and Public Health |
| | Urology |
| | Orthopedic Surgery |

The Registration Department will be open from 8:30 a. m. until 5:30 p. m., Monday, Tuesday, Wednesday and Thursday, June 13, 14, 15 and 16, and from 8:30 a. m. to 12 noon, Friday, June 17.

J. H. J. UPHAM, President.

NATHAN B. VAN ETEN, Speaker, House of Delegates.

OLIN WEST, Secretary.

MEMBERS OF THE HOUSE OF DELEGATES A Preliminary Roster of the Legislative Body of the American Medical Association

The list of members of the House of Delegates for the session is incomplete as a number of the state associations are yet to hold their meetings at which delegates will be elected. The following is a list of the holdover members of the House of Delegates and of the newly elected members who have been reported to the Secretary in time to be included.

STATE DELEGATES

| | |
|-------------------------------------|-----------------------------------|
| ALABAMA | MAINE |

SAN FRANCISCO 1938—CALIFORNIA INVITES YOU

*It lies not East or West
But like a scroll unfurled
It here the hand of God hath hung it,
Down the middle of the world*

A coast line of more than 1 000 miles 157 000 square miles in area, 6 500 000 people, balmy semitropical climate and snow-clad mountains, fertile valleys, forest lands and state and national parks, ocean shore resorts and inland vacation grounds—all of nature's resources essential to man's comfort happiness, business and pursuit of avocation—that is California

San Francisco 475 square miles in area is located on a peninsula with the Pacific ocean on the west and the bay on the north and east forming the largest inland harbor in the world The San Francisco Oakland Bay Bridge and the Golden Gate Bridge acknowledged engineering feats, have recently provided avenues of quicker access to the mainland, displacing the famed ferries of former days

In the heart of the city within walking distance of the leading hotels, is the Civic Center, bounded by Van Ness Fulton, Hyde and McAllister streets—four by two city blocks in area Here are located the Civic Auditorium Memorial Opera House,

SAN FRANCISCO

Historians poets and artists have vied in their descriptions of San Francisco but the city itself surpasses description In June San Francisco's maximum and minimum temperature is from 67 to 50 degrees The days are usually bright and sunny the nights cool with no rain and a minimum of fog in the early morning The visitor will do well to have a light top coat for weather emergencies

Veterans Memorial Building City Hall City Health and Public Library buildings and State and Federal buildings In the auditoriums of these buildings all the meetings and exhibits will be held

The visitor to San Francisco cannot obtain the full savor of the city without having enjoyed the hospitality and comforts of its fifty-four first class hotels and three hundred famed restaurants For this session the local committee has under reservation by contract five thousand rooms in first class

hotels, with additional accommodations available should the attendance registration demand

Golden Gate Park, with 1,013 acres in the heart of the city, provides scenic beauty, trees, flowers, a polo field, playgrounds, a museum a zoo, a tea garden a bandstand, ball and rugby fields, bridle paths, lakes, fountains and statues. The famed harbor of San Francisco Bay is seventy miles long and from four to ten miles wide, connected with the Pacific only by the Golden Gate, a strait a mile across its narrowest point.

The hills of San Francisco give to the city its picturesque effect. Of these hills, Telegraph, Russian, Nob Hill and Twin Peaks are the more important. Each has its own particular and attractive views.

At the Presidio, the headquarters of the corps area, the federal troops are stationed. Here also is one of the army's

than a combination of Eastern states, are centered in the association headquarters at 450 Sutter Street, San Francisco.

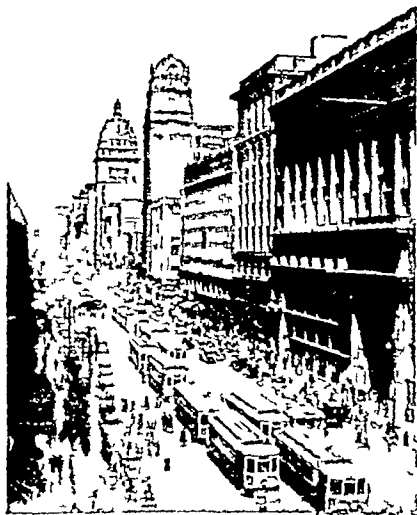

Historical records show that organization of the San Francisco County Medical Society was "unsuccessfully attempted on June 22, 1850, being preceded by the successful formation in Sacramento of a medical society in May of 1850 and by a more or less inconsequential group in Los Angeles in January, 1850. In San Francisco on Nov. 17, 1853, a county medical society was eventually formed, sixty-three members enrolling."

The San Francisco County Medico-Chirurgical Association was mentioned in the first volume of the *Medical Press* which reported that "this society was organized in August 1885. Though its proceedings have been marred by considerable discord, it has still done much in the cause of the profession. This association is and always has been the only working

largest hospitals the Letterman General Hospital. Situated along the bay and the Golden Gate a drive through this army post with its tree-lined drives officers' homes hospital parade grounds cemetery and administration buildings never fails to evoke expressions of delight and admiration. Beyond the Presidio toward the sea is the great coast artillery post Fort Winfield Scott defending the entrance to San Francisco Bay.

Fisherman's Wharf, the Embarcadero, Chinatown, Yacht Harbor, Funston Field and the Court of Honor comprise additional points of interest.

MEDICAL CENTERS

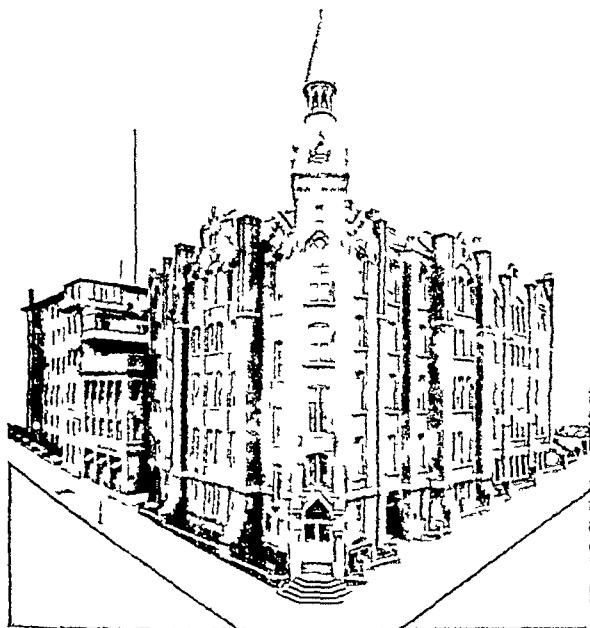

The California Medical Association with more than 6,100 members representing 85.5 per cent of the state's licensed resident physicians is the fourth unit in size in the federation of medicine. Its thirty-nine county units, some of them larger

medical society in this city. This second reference seems to justify the inference that two medical societies were active in San Francisco during the early days. This supposition receives support from editorial comments.

San Francisco Medical Society.—This we believe was the first medical society formed in this city. It has however only been a society in name for the most part. During the presidency of Prof. Henry Gibbons however it was brought into a state of considerable usefulness. Quite a number of very interesting meetings were held with animated discussions upon medical subjects during the year. It has generally been controlled by medical gentlemen who appeared to think their highest duties were performed when they succeeded in carrying the year's elections through untroubledly and had the officers duly announced in all our daily papers.

At first meetings of the San Francisco County Medical Society were held in various halls about the downtown district. After the earthquake and fire of 1906, quarters were rented in the Butler Building at the corner of Stockton and Geary streets, and in 1918 the society moved to the Medical Building, at the corner of Bush and Hyde streets. From the earliest records one finds constant expression of the wish to own its own home. In 1926, largely through the efforts of the late Reginald Knight Smith, the present home was purchased. It was formerly a private residence and is unquestionably the finest building of its type in San Francisco. In spite of the fact that no alterations have been made in the building, it is admirably suited to the needs of the medical society for the holding of its meetings, for its administration headquarters and for the housing of its splendid library.

One of the achievements of the Alameda County Medical Association during the past year has been the growth of its Insurance Association of Approved Hospitals. The following facts are based on figures as of Dec 1, 1937. There are approximately 9,000 members and 454 claims filed amounting

STANFORD UNIVERSITY SCHOOL OF MEDICINE
SAN FRANCISCO

to \$29,106.42 during the past year. The average hospital stay is 7.78 days and the average cost per day is \$8.15. The inclusion of San Francisco, Contra Costa and San Mateo counties has played an important part in the year's growth. The hospitals under contract with this association include:

Alameda County: Peralta, Alta Bates, Providence East, Oakland, Berkeley General, Samuel Merritt and Alameda Sanitarium.

Contra Costa: Antioch, Concord, Martinez and Richmond Cottage.

San Francisco: Children's, Green's Eve, Mary's Help, Mount Zion, St. Joseph's, St. Luke's, St. Mary's, Stanford and University of California.

San Mateo: Mills Memorial.

The Alameda County Medical Association part pay plan continues to function efficiently with 100 per cent cooperation from the members. Sponsored by the antitubercular association of this county, material for tuberculin tests is available to any physician requesting it.

Clinic activities at the various hospitals include an obstetric clinic at Providence, a general pediatric clinic at Children's and a general clinic at the Berkeley General and a cancer clinic and dermatology clinic at Alameda County Hospital. There is keen interest on the part of the members in these various clinics.

During the past year regular monthly meetings of the Alameda County Medical Association have been held and well balanced programs have been presented. Subjects of interest to the greater majority were selected. Officers and members of

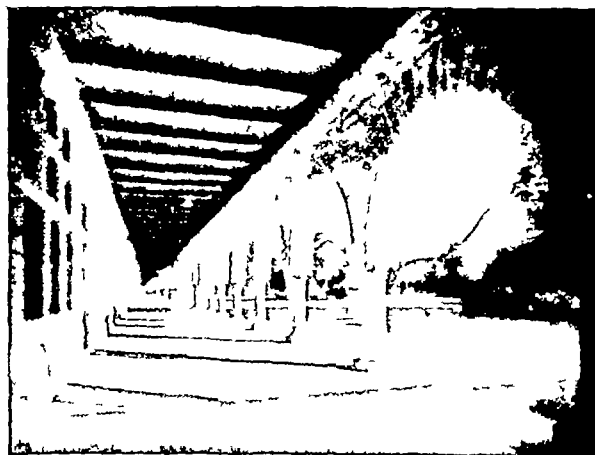

SAN FRANCISCO SKYLINE AND THE FERRY
BUILDING

the council entertained Dr. Olin West, Secretary of the American Medical Association, and on another occasion the director of the Bureau of Medical Economics of the American Medical Association was our guest.

The first annual hobby show was presented by some of our talented members and gave pleasure to all who attended. The beautiful work produced in such varied fields was surprising.

The publicity committee of the association is becoming more active and efficient. The cooperation between the newspapers,

STANFORD UNIVERSITY QUADRANGLE PALO ALTO

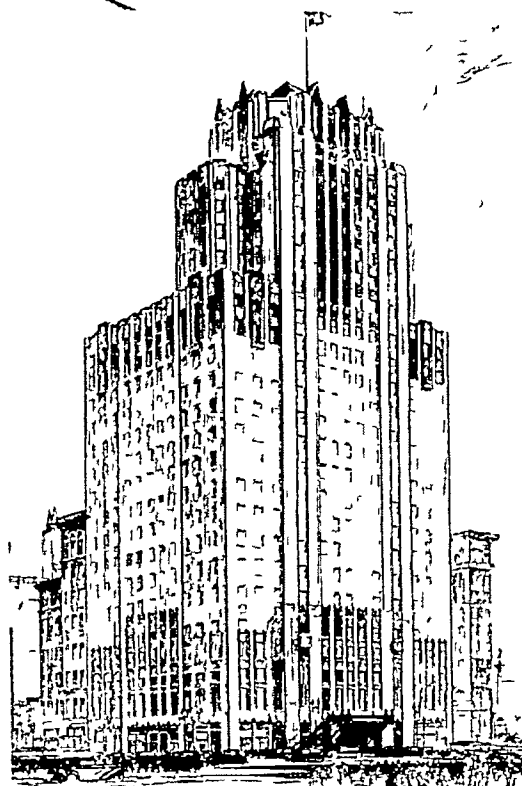

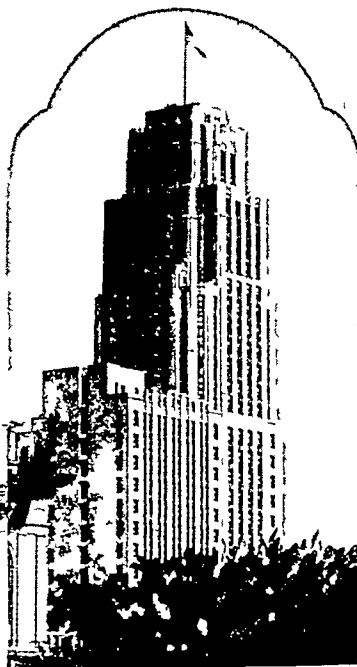

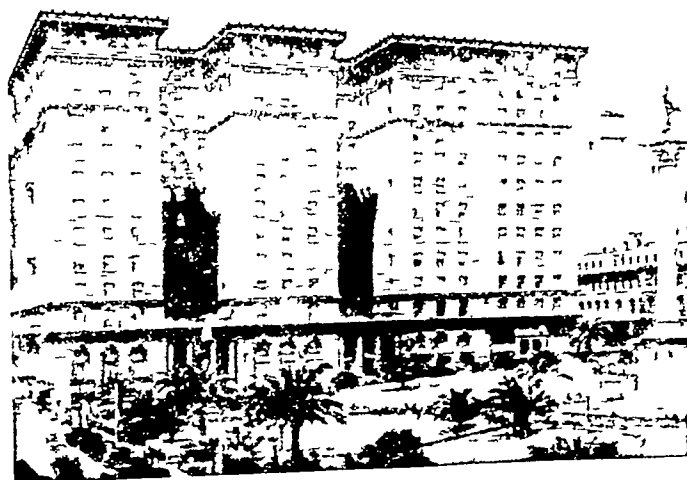

doctors and hospitals is evidence that such friendly cooperation will provide more accurate medical information and will tend to lessen the amount of misinformation published. Such censorship of reports will be of great benefit to both medical practitioners and the public.

The Alameda County Medical Association has cooperated to the fullest degree with the other medical organizations in the state in furthering the understanding of the significance of the aims of scientific medicine for the benefit of the body politic.

In addition to these San Jose, at the south end of the bay fifty miles from San Francisco, Contra Costa, Vallejo and Marin compose the Bay area county medical organizations.

MEDICAL COLLEGES

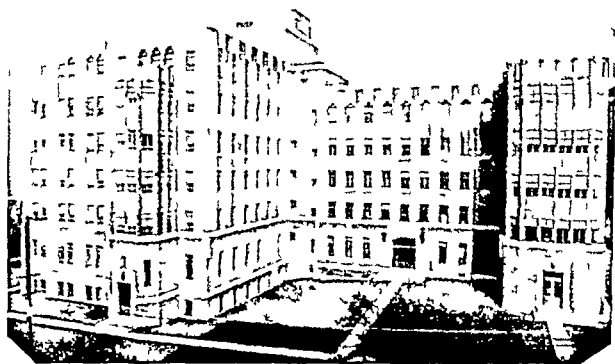

Toland Medical College established in 1862, was absorbed by the University of California in 1872 and became its medical school. In 1898 buildings were erected on the San Francisco campus of the university, from which the present Medical Center has developed. All the divisions of the medical school, except those of the first year, are housed at the Medical Center. The University Hospital of 300 beds and the outpatient department with 185,000 annual visits are conducted as clinical teaching

cine, Obstetrics and Gynecology, Pathology, Pediatrics, Pharmacology and Therapeutics, Physiology, Public Health and Preventive Medicine, and Surgery. The first four trimesters of undergraduate teaching are done at the university campus and the remainder of the teaching is done at Stanford University School of Medicine, Sacramento and Webster streets, San Francisco. The medical school owns and controls Lane Hospital and Stanford University Hospital, and the university owns and controls Lane Medical Library, which is one of the foremost medical libraries of this country, containing more than eighty-six thousand volumes. The medical school accepts only sixty students in each of its classes and requires a one year internship before awarding the degree of doctor of medicine. The medical

Above PSYCHOPATHIC BUILDING (left) AND BUILDINGS NO. 1 AND NO. 2 MENS WARDS

activities. The first year departments of anatomy, physiology and biochemistry are in the Life Sciences Building on the Berkeley campus of the university. Besides the Medical School, the Medical Center, a sixteen-acre tract of land includes the Colleges of Dentistry and Pharmacy, the Training School for Nurses and the George Williams Hooper Foundation, which is actively engaged in medical research. The clinics of the College of Dentistry are closely coordinated with those of the medical outpatient department.

Stanford University School of Medicine came into being in 1908 when all the properties and equipment of the Cooper Medical College founded in 1882 were transferred to Stanford University. The medical school is an integral part of Stanford University and has the following eleven departments: Anatomy, Bacteriology and Experimental Pathology, Chemistry, Medi-

cine, Obstetrics and Gynecology, Pathology, Pediatrics, Pharmacology and Therapeutics, Physiology, Public Health and Preventive Medicine, and Surgery. The medical school directs an outpatient clinic which receives in the neighborhood of 170,000 patient visits annually. The medical school is financed entirely by Stanford University endowment fund and private donations.

SAN FRANCISCO HOSPITAL

The San Francisco Hospital, an institution within the department of public health of the city and county of San Francisco and deriving its funds for operation from the public treasury, is limited to accepting only those patients who are unable to provide for their own care in a private hospital.

It is a general hospital with a capacity of 1,400 bed-officers in addition to general medical and surgical services, a tuber-

culosis division, an isolation division for the care of the communicable diseases and a new psychopathic unit. As adjuncts, city physicians, giving care in the home to those who cannot afford to have the services of a privately practicing physician are on call through the Social Service Division, and an outpatient obstetric service is given to expectant mothers in their homes when they too cannot have private medical care. Although a follow-up care for discharged patients is given no general outpatient care is provided. The two university medical schools give the city and county of San Francisco invaluable service, in that members of the faculties of these educational centers serve as visiting staff members.

The visiting staff consists of 150 physicians and surgeons appointed by the director of public health from the medical teaching staffs of the University of California Medical School and Stanford University Medical School.

THE EMERGENCY HOSPITALS

The Emergency Hospital Service, so frequently linked with the police department of most large cities, is also a part of the department of public health in San Francisco.

The service includes twenty-four hour service in each of six emergency hospitals located in various parts of the city. Fourteen radio equipped ambulances are operated, each manned with a driver and a trained hospital steward. A surgeon and a nurse working on an eight hour shift, are in constant attendance at the Emergency Hospital. The administrative staff under the director of public health, is the chief surgeon and assistant chief surgeon, one of whom is always on call, and the chief steward. More than 70,000 cases were handled during the past year with 32,000 ambulance calls.

THE DEPARTMENT OF PUBLIC HEALTH

In San Francisco the activities of the Department of Public Health include, in addition to those services usually referred to as the strictly preventive and public health functions, the institutional services, comprising the San Francisco Hospital (a general hospital), the Laguna Honda Home (for the aged and infirm), the Hassler Health Home (for the tuberculous) and the Emergency Hospital Service (including ambulance

BOARD OF HEALTH BUILDING CIVIC CENTER

service). This administrative setup has been in effect in San Francisco for many years and was incorporated in the charter of 1900 and the new freeholders' charter of 1932.

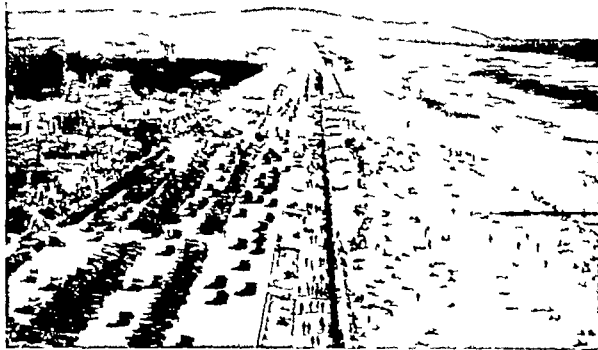

While under the charter of 1900 the department was administered by the board of health through its executive officer, the health officer, the new freeholders' charter of 1932 centralizes the responsibility in the director of public health. The Health Advisory Board made up of three physicians, a dentist and three laymen appointed by the chief administrative officer to terms of four years each, has only advisory power.

Housed since 1932 in a modern building erected for its sole use, the Department of Public Health has a building of which it may well be proud and which is undoubtedly one of the finest in the United States.

SUGGESTIONS FOR PERSONAL COMFORT IN CALIFORNIA

1 In San Francisco the temperature in June varies between 50 and 70 degrees. The afternoons and nights are cool. Bring a light spring suit and top coat. Summer suits are not advisable.

2 The June temperature of Los Angeles varies from 70 to 80 degrees with cool nights. Summer clothes add to personal comfort.

THE OCEAN BEACH BELOW CLIFF HOUSE
SAND DUNES IN DISTANCE

3 Northern California along the coast and redwood highways has a temperature comparable to June in the Middle West or East.

4 On the coast highway south of San Francisco the temperature ranges from ten to twenty degrees higher than in San Francisco.

5 Inland in the Sacramento and San Joaquin valleys the temperature ranges from 70 to 90 degrees, with hot spells during which the temperature reaches from 100 to 110. In the mountain regions and national parks, the days are comfortably warm with cool nights.

6 California's automobile highways are maintained in almost perfect condition. This is especially true of the main trunk lines. They are well posted, and curves and steep grades are well marked. It driving bring your car ownership certificate and driver's license as you will be stopped at the borders and given a special permit without charge. There is a federal government fee of \$2 to enter national parks. This is paid at any entrance roadgate.

7 Sun glasses add to personal comfort.

CALIFORNIA

The hurried two to four day tourists' itinerary is entirely too brief to gain a true picture of the state. One will never regret the time spent in a more extended visit to California's points of special interest. The suggestion is advanced that plans be made to travel direct without intervening stops, in order that time may be allotted to visits to San Diego, Los Angeles, the Coast Highway, Santa Barbara, Monterey Bay and Del Monte, the Santa Clara Valley, the Valley of the Moon, Big Basin, Yosemite National Park, Redwood Highway, Mare Island, Oakland, Sacramento Valley and the Sierra resorts. From timberlands with its lakes and streams, fertile valleys, grazing plains, mountainous regions, state parks and playgrounds and sportslands to the metropolitan centers, California affords the tourist and vacationist an ever varying, unending opportunity of rest, joy and inspiration. To see to know, to appreciate fully, one needs to include these centers in a visit to California.

TRANSPORTATION

Railroad Rates to San Francisco

Because of the reduction in one way fares to three cents a mile for travel in sleeping and parlor cars, which closely approximates the former convention fare basis, the use of convention fares has been discontinued in the territories of the Central Passenger, Trunk Line and New England Passenger Associations.

In the territory of the Transcontinental Passenger Association and in that part of the territory of the Western Passenger Association east of and including El Paso, Texas, Albuquerque, N. M., Ogden and Salt Lake City, Utah, and the state of Montana the following round trip fares, for which no certificates of any kind will be necessary, have been authorized from the points named to San Francisco: Chicago, \$90.30, Kansas City, Mo., \$75.60, Memphis, Tenn., \$89.25, Minneapolis, \$90.30, New Orleans, \$89.25, Omaha, \$75.60, St. Louis, \$85.60, St. Paul, \$90.30. These fares include the privilege of going by any authorized route and returning by any other authorized route. They are subject to change without notice.

We have also been informed that the following round trip fares for which no certificate of any kind will be necessary have been authorized from the points named to San Francisco but are subject to change without notice: Washington, D. C., \$130.40, Boston, Mass., \$148.55, Grand Rapids, Mich., \$101, Buffalo, N. Y., \$120.65, Cincinnati, Ohio, \$105.45, Philadelphia, Pa., \$136.10, Norfolk, Va., \$131.10, Birmingham, Ala., \$97.90, Lexington, Ky., \$102.70, Nashville, Tenn., \$96.55, Baltimore, Md., \$130.40, Detroit, Mich., \$106.75, Albany, N. Y., \$137.35, New York, N. Y., \$141.50, Cleveland, Ohio, \$110, Pittsburgh, Pa., \$117.40, Parkersburg, W. Va., \$117.10, Atlanta, Ga., \$104.90, Louisville, Ky., \$99.95.

All members who expect to attend the session are urged to confer with their home ticket agents, who will be able to give them more specific information regarding fares and routes.

Special Trains to San Francisco With Stop-Overs

De luxe special trains restricted to physicians, their families and friends are available to San Francisco for the annual session, leaving Chicago June 6. There will be stop-overs at Lamy, N. M., for a sightseeing trip through the Indian Pueblo district by motor coach and at the Grand Canyon in Arizona and at Los Angeles then the party will go by steamship to Avalon on Santa Catalina Island, returning to Los Angeles, and on to San Francisco by train, arriving 9 a. m., Monday, June 13. On the return trip east there is a choice of two routes each with stop over sightseeing trips. Returning, route one is through Portland, Seattle, Victoria, Vancouver, Canadian Rockies, Lake Louise and Banff. Route two is by Yellowstone National Park, Salt Lake City, Royal Gorge, Colorado Springs and Denver. By route one the train arrives in Chicago at 4:40 p. m., June 25 and by route two, June 27, at 9:23 a. m. Twenty-five state medical societies have become interested in these special trains for physicians, and a descriptive folder giving additional information about the sightseeing side trips may be had from the secretaries of these state societies or from the American Express Travel Service, 180 North Michigan Avenue, Chicago.

Chicago Medical Society Special

The Chicago Medical Society Special train will leave Chicago from the Union Station at 9 p. m., Thursday, June 9, arriving in San Francisco at 8:30 a. m., Sunday, June 12. The train will be operated on a fast schedule and no excess fare will be charged. Members of the American Medical Association, their families and friends are cordially invited to join this group. Dr. Frank P. Hammond, 30 North Michigan Avenue, Chicago, is the chairman of the transportation committee of the Chicago Medical Society.

Golfers' Special

The Golfers' Special will bring you to San Francisco a most pleasant way. This American Medical Golfing Association tour includes an ocean voyage from New York to New Orleans (six days) on the S. S. Dixie sailing June 1. The first game of golf will be played in New Orleans on June 7 followed by five games on excellent courses on the outgoing trip with stops and sight-seeing at Houston, Galveston and San Antonio, Texas and Los Angeles including Hollywood and Del Monte, Calif.

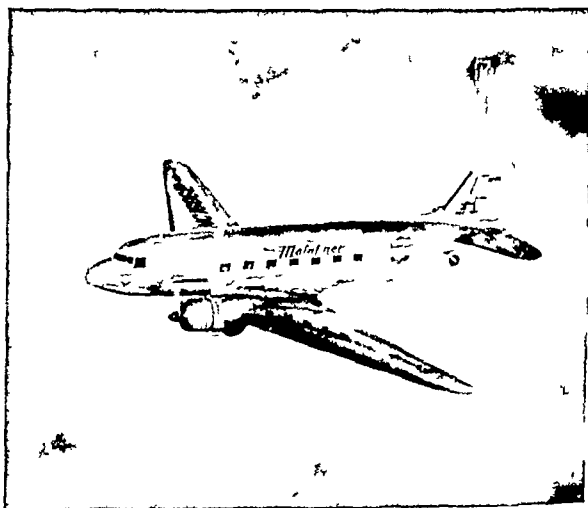

The return journey will be via Portland, Seattle, Vancouver, Lake Louise and Banff, with two additional games of golf, more sight-seeing and a steamship voyage up Puget Sound. Non golfers as well as golfers (and their ladies) are invited.

If you can't spend the time for the ocean voyage from New York, join the Golfers' Special at New Orleans on June 7. If you can't join the Golfers' Special on the trip to San Francisco plan on taking the return journey through the glorious North West, including Vancouver, Lake Louise and Banff.

Drop a card for detailed information and rates to Mr. W. J. Burns, Executive Secretary, Michigan State Medical Society, 2020 Olds Tower, Lansing, Mich.

Automobile Travel

The California State Automobile Association suggests three automobile routes from Chicago to San Francisco, namely, a southern, an overland and a northern route. The southern route leads one through St. Louis, Oklahoma City, Albuquerque and Los Angeles to San Francisco, and a detour may be made to the south rim of the Grand Canyon, the overland route, through Omaha, Cheyenne, Salt Lake City, Reno and Oakland to San Francisco, the northern route through Minneapolis, Fargo, Helena, Spokane, Seattle, Portland and San Rafael to San Francisco, and a detour may be made to Yellowstone National Park.

FLYING TO SAN FRANCISCO

Air Travel

Plans are being made to provide frequent airplane service between New York, Chicago, Denver and San Francisco at the time of the annual session. California is just a "good night's sleep," from New York, Chicago and other eastern cities because of fast overnight sleeper plane service.

In addition to overnight schedules from coast to coast, passengers may choose convenient scenic daylight flights. For those planning to visit other points on the Pacific Coast either before or after the session there is a border to border service linking Vancouver, Seattle, Tacoma, Portland, San Francisco, Oakland, Los Angeles and San Diego.

In some instances it is possible for passengers, in traveling by plane to San Francisco to go to Los Angeles at no extra cost. Commuter service, with seven flights daily, is operated between San Francisco and Los Angeles, the 330 mile nonstop flight requiring only two hours.

Many California cities have air service, and planes land close to all western vacation lands. Yosemite National Park is but a short distance from Fresno, fishing and hunting grounds are conveniently reached from Medford or Portland and Tacoma and Seattle are gateways to Mount Rainier National Park.

It is suggested that those interested in traveling to San Francisco by airplane consult the agents of the airlines serving their respective territories.

REGISTRATION

The Bureau of Registration will be located in the Auditorium in Civic Center Grove street, between Polk and Larkin streets. Members of the Subcommittee on Registration of the Local Committee on Arrangements will be on hand to assist those who desire to register. A branch postoffice in charge of government postoffice officials will be available for visitors, and an information bureau will be operated in connection with the Bureau of Registration.

Who May Register

Only Fellows, Affiliate, Associate and Honorary Fellows and Invited Guests may register and take part in the work of the sections. Fellows of the Scientific Assembly are those who have, on the prescribed form, applied for Fellowship, subscribed to THE JOURNAL, and paid their Fellowship dues for the current year. The annual Fellowship dues provide a subscription to THE JOURNAL for one year. Fellowship cards are sent to all Fellows after payment of annual dues and these cards should be presented at the registration window. Any who have not received cards for 1938 should secure them at once by writing to the American Medical Association, 535 North Dearborn Street, Chicago.

Members in Good Standing Eligible to Apply for Fellowship in the Association

Members in good standing in component county medical societies are members of constituent state associations and of the American Medical Association. All members in good standing may apply for Fellowship in the Scientific Assembly and are urged to qualify as Fellows before leaving home in order that pocket cards may be secured and brought to San Francisco so that registration can be more easily and more promptly effected.

Application forms may be had on request.

Those subscribers to THE JOURNAL who have not received pocket cards for 1938 should write to the American Medical Association for application blanks and information as to further requirements.

Register Early

Fellows living in San Francisco, as well as all other Fellows who are in San Francisco on Monday and Tuesday, should register as early as possible. The names of those who register will be included in the issue of the *Daily Bulletin* appearing the next day and this will enable visiting physicians to find friends if they have registered.

Suggestions That Will Facilitate Registration

Fellows should fill out completely the spaces on both sections of the front of the *white* registration card which will be found on the tables in front of the Registration Bureau.

Physicians who desire to qualify as Fellows should fill out completely the spaces on both sections of the front of the *blue* registration card and sign the application on the back. These cards will be found on the tables.

Entries on the registration cards should be written plainly or printed as the cards are given to the printer to use as copy for the *Daily Bulletin* published on Tuesday, Wednesday, Thursday and Friday of the week of the session.

Fellows who have their pocket cards with them can be registered with little or no delay. They should present the filled out *white* registration card together with their pocket cards at one of the windows marked "Registration by Pocket Card." There the clerk will compare the two cards, stamp the pocket card and return it and supply the Fellow with a badge, a copy of the official program and other printed matter of interest to those attending the annual session.

As previously stated it will assist in registering if those who desire to qualify as Fellows will file their applications and qualify as Fellows by writing directly to the American Medical Association, 535 North Dearborn Street, Chicago, so that their Fellowship may be entered not later than May 21. Any applications that are received later than May 21 will be given

prompt attention but the Fellowship pocket card may not reach the applicant in time for him to register at the San Francisco session.

It will be possible for members of the organization to qualify as Fellows at San Francisco. In order to do this, applicants for Fellowship will be required to fill out both sections of the front of the *blue* registration card and to sign the formal application that is printed on the reverse side of the card. It is suggested that those members who apply for Fellowship at San Francisco bring with them their state membership cards for 1938. The state membership card should be presented along with the filled in *blue* registration card at the window in the booth marked "Applicants for Fellowship and Invited Guests."

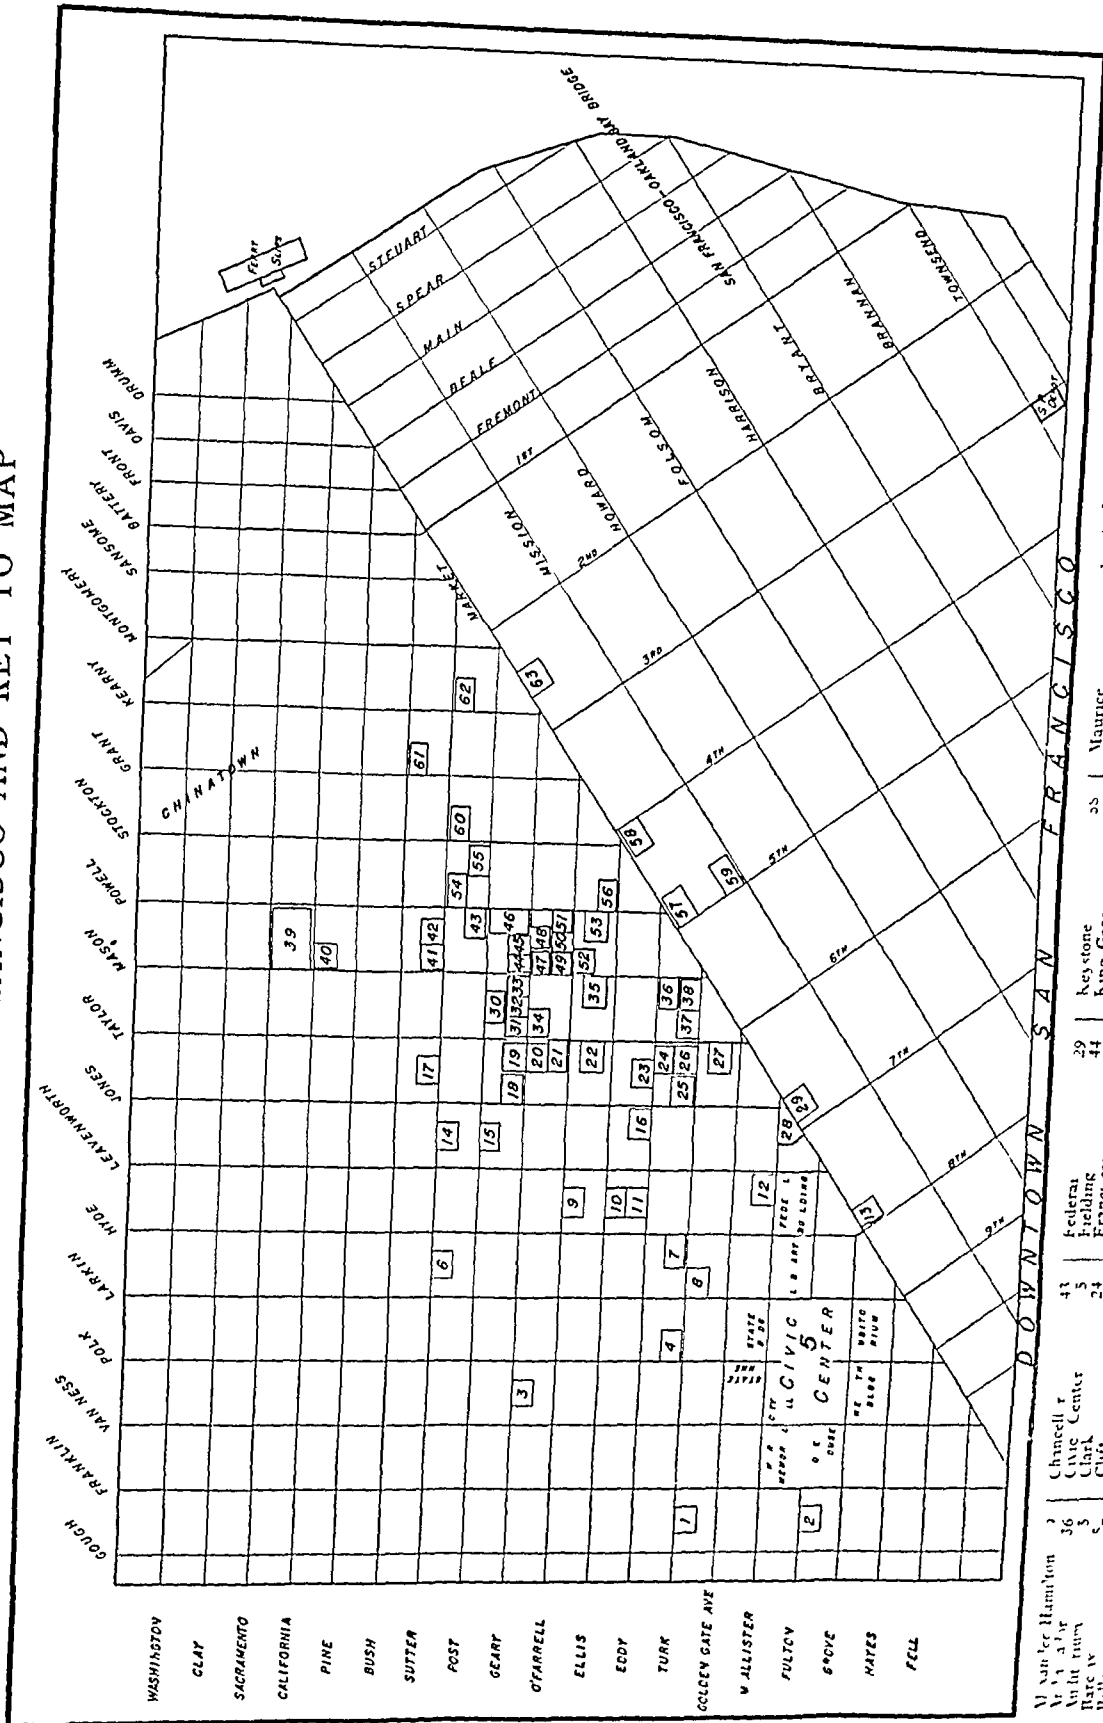

YOSEMITE FALLS ABOUT 187 MILES FROM SAN FRANCISCO—
THE UPPER FALL ALONE DROPS 1,430 FEET

As already stated registration can be effected more easily and more promptly if members will qualify as Fellows before leaving home.

Registration for General Officers and Delegates at the Hotel Sir Francis Drake

General Officers of the American Medical Association and members of the House of Delegates may register for the Scientific Assembly in the French Room adjacent to the Empire Room of the Hotel Sir Francis Drake. This arrangement is made for the convenience of the members of the House of Delegates which will convene on Monday morning at 10 o'clock in the Empire Room of the Hotel Sir Francis Drake. Delegates are requested to register for the Scientific Assembly before presenting credentials to the Reference Committee on Credentials of the House of Delegates. Registration of delegates for the Scientific Assembly will begin at 8 o'clock Monday morning, June 13, and delegates are urged to register early so that all members of the House of Delegates may be seated in time for the opening session of the House.

GOLF TOURNAMENT

The American Medical Golfing Association will hold its twenty-fourth annual tournament at the beautiful San Francisco Golf and Country Club on Monday, June 13. Members may tee off from 7 30 a m to 2 30 p m.

FIFTY TROPHIES AND PRIZES

Thirty-six holes of golf will be played in competition for the fifty trophies and prizes in the nine events. Trophies will be awarded for the Association Championship, thirty-six holes gross, the Will Walter Trophy, the Association Handicap Championship, thirty-six holes net, the Detroit Trophy, the Championship Flight, First Gross, thirty-six holes, the St Louis Trophy, the Championship Flight, First Net, thirty-six holes, the President's Trophy, the Eighteen Hole Championship, the Golden State Trophy, the Eighteen Hole Handicap Championship, the Ben Thomas Trophy, the Maturity Event, limited to Fellows over 60 years of age, the Minneapolis Trophy, the Oldguard Championship, limited to competition of past presidents, the Wendell Phillips Trophy, and the Kickers Handicap, the Atlantic City Trophy. Other events and prizes will be announced at the first tee.

FELLOWS IN EVERY STATE OF THE UNION

Dr Walt P Conaway of Atlantic City, N J, is president, and Drs E S Edgerton of Wichita Kan, and George Washington Hill of Chicago are vice presidents of the A M G A, which was organized in 1915 by Drs Will Walter, Wendell Phillips and Gene Lewis and now totals 1,400 members representing every state in the Union. The living past presidents include Drs Thomas Hubbard of Toledo, Fred Bailev of St. Louis, Edward Martin of Media Pa, Robert Moss of LaGrange, Texas, Charlton Wallace of New York, Will Walter of Charlottesville, Va, James Eaves of Oakland, Calif, D Chester Brown of Danbury, Conn, Samuel Childs of Denver, W D Shelden of Rochester, Minn, Walter Schaller of San Francisco, Edwin Zabriskie of New York, Frank A Kelly of Detroit, John Welsh Croskey of Philadelphia, Homer K Nicoll of Chicago, Charles Lukens of Toledo, M M Cullom of Nashville and W Albert Cook of Tulsa, Okla.

DR JAMES W MORGAN HEADS SAN FRANCISCO
GOLF COMMITTEE

The San Francisco committee is under the chairmanship of Dr James W Morgan 384 Post Street San Francisco. He

will be assisted by Drs George A Gray, Ernest D Chipman, William G Moore and George McClure.

APPLICATION FOR MEMBERSHIP

All male Fellows of the American Medical Association are eligible and cordially invited to become members of the A M G A. Write the Executive Secretary, William J Burns, 2020 Olds Tower, Lansing, Mich, for an application blank. Participants in the A M G A tournament are required to furnish their home club handicap, signed by the club secretary. No handicap over 30 is allowed, except in the Kickers (Blind Bogey). Only active Fellows of the A M G A may compete for prizes. No trophy is awarded a Fellow who is absent from the annual dinner.

A MAGNIFICENT COURSE

The twenty-fourth tournament of the American Medical Golfing Association at the San Francisco Golf and Country Club promises to be a pleasant affair. The club is one of the most elaborate in the country. The A M G A officers anticipate that some two hundred medical golfers from all parts of the United States will play in San Francisco on June 13.

GOLFERS TOUR

The American Medical Golfing Association has arranged a tour including an ocean voyage from New York to New Orleans on the S S *Dirie*, sailing June 1. The first game of golf of the tour will be played in New Orleans June 7, other games will be played on excellent courses on the way to San Francisco with stopovers at Houston, Galveston and San Antonio, Texas, and Los Angeles. On the return trip by way of Portland, Seattle, Vancouver, Lake Louise and Banff there will be two additional games of golf, more sight-seeing and a water trip on Puget Sound. Nongolfers as well as golfers and their ladies are invited to take this trip, and if time does not permit making the ocean voyage the 'Golfers Special' may be joined at New Orleans, June 7, perhaps others who will be unable to make the outgoing trip can make the return journey through the northwest, including Vancouver, Lake Louise and Banff. Further information and rates may be had from Mr W J Burns 2020 Olds Tower Lansing Mich.

THE PROGRAMS OF THE SECTIONS

Outline of the Scientific Proceedings—The Preliminary Program and the Official Program

The following papers are announced to be read before the various sections. The order here is not necessarily the order that will be followed in the Official Program, nor is the list complete. The Official Program will be similar to the programs issued in previous years and will contain the final program of each section with abstracts of the papers, as well as lists of committees, program of the Opening General Meeting, list of entertainments, map of San Francisco, and other information. To prevent misunderstandings and protect the interest of advertisers, it is here announced that this Official Program will contain no advertisements. It is copyrighted by the American Medical Association and will not be distributed before the session. A copy will be given to each Fellow on registration.

Discussion to be opened by CHEVALIER JACKSON, Philadelphia J MACKENZIE BROWN, Los Angeles and W B CHAMBERLIN, Cleveland

Malignant Disease of the External Ear, with a Report of Eight Cases (Lantern Demonstration) FRANK R SPENCER, Boulder, Colo
Discussion to be opened by H P Mosher, Boston, and GORDON B NEW, Rochester, Minn

Benign Granuloma of the Nose (So Called Sarcoid) Report of a Case (Lantern Demonstration) FRANK B KISTNER and THOMAS D ROBERTSON, Portland Ore
Discussion to be opened by MATTHEW N HOSMER, San Francisco, and JOHN E WIRTH, Seattle

Friday, June 17—2 p m**Election of Officers**

The Petrous Apex of the Temporal Bone and Its Relations (Lantern Demonstration)

WILLIAM J MELLINGER, Santa Barbara, Calif

Discussion to be opened by J PARSONS SHAEFFER, Philadelphia, OLOF LARSELL, Portland Ore and HENRY J

PROFANT, Santa Barbara, Calif

Malignancy of the Nasopharynx (Lantern Demonstration) DUFWIN H BROWNELL and I JEPOMIE HAUSER, Ann Arbor, Mich

Discussion to be opened by JOSEPH C BRICK, Chicago and JOHN H CHILDREY, San Francisco

Surgical Pathology of Sinusitis (Lantern Demonstration) HERMAN Z SEMPEROV, Los Angeles

Discussion to be opened by ROY F WILSON, Oakland Calif, and RAYMOND O DART, San Francisco

Cerebrospinal Rhinorrhea with a Report of a Case Cured by Operation (Lantern Demonstration)

DAVID R HUBER, San Diego Calif

Discussion to be opened by HOWARD C SHAEFFER, San Francisco, WELLS P LACROIX, New York, and CHESTER H BOWEN, Los Angeles

Atrophic Rhinitis (Lantern Demonstration) C C CHURTO, Atlantic City, N J

Discussion to be opened by FRANK B KISTNER, Portland Ore and ROBERT F RIDPATH, Philadelphia

SECTION ON PEDIATRICS

MEETS IN AUDITORIUM OF OPERA HOUSE CIVIC CENTER

OFFICERS OF SECTION

Chairman—CLIFFORD SWEET, Oakland, Calif
Vice Chairman—EDWARD B SHAW, San Francisco
Secretary—ALBERT D KAISER, Rochester, N Y
Executive Committee—HORTON R CASPARIS Nashville Tenn,
RALPH M TYSON, Philadelphia, CLIFFORD SWEET Oakland,
Calif

Wednesday, June 15—9 a m

Chairman's Address The Opportunities in Pediatric Practice
CLIFFORD SWEET Oakland Calif
Recent Studies in Experimental Lobar Pneumonia (Lantern
Demonstration) OSWALD H ROBERTSON, Chicago
Treatment of Pertussis (Lantern Demonstration)
JAMES A CONNER, Chicago
Discussion to be opened by JOHN M FRAWLEY, Fresno,
Calif, and JOHN J MILLER JR, San Francisco
Further Observations on the Use of Sulfanilamide or Its
Derivatives in the Treatment of Certain Infectious Dis-
eases (Lantern Demonstration)
PERRIN H LONG and ELEANOR A BLISS, Baltimore
Discussion to be opened by FRANCIS SCOTT SMYTH San
Francisco, and THOMAS B COOLEY Detroit
Diagnosis and Treatment of Urinary Infections (Lantern
Demonstration)
HENRY F HELMHOLZ, Rochester Minn
Discussion to be opened by WILLIAM P HERBST, Wash-
ington, D C, and WILLIAM PALMER LUCAS, San
Francisco
Onset and Natural Progress of Allergy in Childhood (Lantern
Demonstration) BRET RATNER New York
Discussion to be opened by MILTON B COHEN, Cleveland

Thursday, June 16—9 a m

JOINT MEETING WITH SECTION ON RADIOLOGY

Sinus Disease in Children (Lantern Demonstration)
W WALTER WASSON, Denver
Sinus Treatment in Children (Lantern Demonstration)
EDWARD C MITCHELL, Memphis, Tenn
Ephedrine in a Physiologic Vehicle and Lateral Head Low
Posture in Treatment of the Nose and Sinuses (Lantern
and Motion Picture Demonstration)
SIDNEY N PARKINSON, Oakland Calif
Discussion to be opened by JOHN J SHEA Memphis
Tenn
Diagnosis and Treatment of Thymus Disease with X-Rays
(Lantern Demonstration)
CLYDE K HASLEY Detroit
Experimental Phases of the Thymus Problem (Lantern and
Motion Picture Demonstration)
L G ROWNTREE and N H EINHORN Philadelphia
Thymus Problem in Children (Lantern Demonstration)
A GRAEME MITCHELL Cincinnati
Discussion to be opened by EDITH BOYD Minneapolis

Friday, June 17—9 a m

Election of Officers

Levels of Control in the Management of Diabetes Mellitus
(Lantern Demonstration)
ROBERT L JACKSON and J D BOYD, Iowa City
Discussion to be opened by IRVINE MCQUARRIE Min-
neapolis and PERCIVAL ALLEN GRAY JR Santa Bar-
bara, Calif
A Criticism of Present Day Newborn Nursery Practice
MANDEL L SPIVEK Chicago
Discussion to be opened by ERNEST WOLFF San Fran-
cisco, and L HOWARD SMITH Portland Ore
Should the Tuberculosis Problem in Children be the Respon-
sibility of the Health Officer or the Pediatrician?
HORTON R CASPARIS, Nashville Tenn
Discussion to be opened by FRANKLIN P GENGENDACH
Denver, and V W SPICKARD Seattle
Allergy of Childhood Prophylaxis, Early Diagnosis and
Treatment W AMBROSE MCGEE Richmond Va
Discussion to be opened by GEORGE PINESS Los Angeles
and MARCARET M NICHOLSON Washington D C
Hematologic Indexes in Normal and Anemic Infants and Chil-
dren (Lantern Demonstration)
KATSUJI KATO Chicago
Discussion to be opened by EDWIN E OSGOOD Portland
Ore and RUSSELL L HADEN, Cleveland

Clinical Effects of Whole Adrenal Gland by Mouth (Lantern
Demonstration) ORVILLE E BARBOUR, Peoria, Ill
Discussion to be opened by E KOST SHELTON, Los
Angeles, and HANS LISSER, San Francisco

SECTION ON PHARMACOLOGY AND THERAPEUTICS

MEETS IN ROOM 1 VETERANS BUILDING CIVIC CENTER

OFFICERS OF SECTION

Chairman—RUSSELL L HADEN, Cleveland
Vice Chairman—ERWIN E NELSON, Ann Arbor, Mich
Secretary—IRVING S WRIGHT, New York
Executive Committee—CHAUNCEY D LEAKE, San Francisco,
N C GILBERT, Chicago, RUSSELL L HADEN, Cleveland

Wednesday, June 15—9 a m

The Use of Crystalline Insulin in the Treatment of Patients
with Severe Diabetes (Lantern Demonstration)
SAMUEL S ALTSHULER, Detroit
Histone Insulin and Allied Insulin Compounds (Lantern Demon-
stration)
PERCIVAL ALLEN GRAY JR, FRITZ EMIL BISCHOFF and
W D SANSUM, Santa Barbara, Calif
Discussion to be opened by H CLARE SHEPHERDSON, San
Francisco
The Treatment of Pellagra by Means of Nicotinic Acid (Lantern
Demonstration)
TOM DOUGLAS SPIES and WILLIAM B BEAN, Cincin-
nati, and ROBERT E STONE, Birmingham, Ala
Discussion to be opened by THOMAS T MACKIE, New
York
Drugs Acting on the Autonomic Nervous System Phenyl and
Substituted Phenyl Alkylamines (Lantern Demonstration)
GORDON A ALLES, Los Angeles
Discussion to be opened by CLINTON H THIENES and
M H NATHANSON Los Angeles
The Choice of a Sympathetic Stimulant for Treating Abnormal
Circulatory States (Lantern Demonstration)
M L TANTER, San Francisco
Discussion to be opened by DAVID A RYLAND, San
Francisco
Visualization of the Pulmonary Circulation in Man by Means
of Peripheral Intravenous Injection (Lantern Demonstra-
tion) GEORGE P ROBB and ISRAEL STEINBERG, New York
Discussion to be opened by EDGAR V ALLEN, Rochester,
Minn

Thursday, June 16—9 a m

SIMPOSIUM ON BLOOD DISCRASIAS

A Symposium on Blood Dyscrasias Is Also Being Presented
on Thursday Afternoon Before the Section on
Pathology and Physiology
Chairman's Address Historical Aspects of the Use of Iron
and Liver in the Treatment of Anemia
RUSSELL L HADEN, Cleveland
The Culture of Human Marrow as an Aid in the Evaluation
of Therapeutic Agents (Lantern Demonstration)
EDWIN E OSGOOD Portland, Ore
The Treatment of Pathologic Hemorrhage (Lantern Demon-
stration) HAROLD W JONES, Philadelphia
The Treatment of Thrombocytopenic Purpura
NATHAN ROSENTHAL, New York
The Treatment of Pernicious Anemia
WILLIAM P MURPHY, Boston
The Treatment of Iron Deficiency Anemias (Lantern Demon-
stration)
W M FOWLER and ADELAIDE P BAREK, Iowa City

Friday, June 17—9 a m

Election of Officers

Sodium Chloride Tolerance in Chronic Nephritis with Some
Observations on Potassium and Sulfate Ions (Lantern
Demonstration) M HERBERT BARKER Chicago
Discussion to be opened by THOMAS ADDIS San Fran-
cisco and MYRON PRINZMETAL, Los Angeles
Chronic Effects of Ingested Lead and Arsenic (Lantern Demon-
stration) HERBERT O CALVERY Washington D C
Discussion to be opened by FLOYD DELOS San Francisco,
ERWIN E NELSON New Orleans and P J HANZLICH,
San Francisco
The Evaluation of Drugs Commonly Employed as Diagnostic
Aids in Clinical Medicine
S R METTIEP and CHAUNCEY D LEAKE San Francisco
Discussion to be opened by ARTHUR L PROSMITH San
Francisco

The Use of Serum in the Higher Types of Pneumonia (Lantern Demonstration)

NORMAN H. PLUMMER, New York

Discussion to be opened by RUSSELL L. CECIL, New York
The Use of Adrenal Hormones in the Treatment of Asthma, Asthma and Tuberculosis (Lantern Demonstration)

F. M. POTTENGER SR., Monrovia, Calif.

Further Clinical Observations on Therapeutic Effectiveness and Toxicity of Sulfanilamide and Several Related Compounds (Lantern Demonstration)

E. G. BANNICK, A. E. BROWN and F. P. FOSTER, Rochester, Minn.

Discussion to be opened by DWIGHT L. WILBUR, San Francisco, and EDWIN E. OSGOOD, Portland, Ore.

SECTION ON PATHOLOGY AND PHYSIOLOGY

MEETS IN ROOM 1 VETERANS BUILDING CIVIL CENTER

OFFICERS OF SECTION

Chairman—ROY R. KRACKE, Emory University, Ga.

Vice Chairman—MAURICE B. VISSCHER, Minneapolis

Secretary—J. J. MOORE, Chicago

Executive Committee—HENRY C. SWEANY, Chicago, W. E. GARREY, Nashville, Tenn., ROY R. KRACKE, Emory University, Ga.

Wednesday, June 15—2 p. m.

Pathology of the Placenta, with Particular Reference to Infarcts and Their Relation to the Toxemias of Pregnancy (Lantern Demonstration)

R. A. BARTHOLOMEW, Atlanta, Ga.

Arterial Occlusions with Aseptic Necrosis of Bones (Lantern Demonstration)

EDWIN F. HIRSCH, Chicago

Ulcerative Gastritis and Residual Lesions (Lantern Demonstration)

H. E. ROBERTSON, Rochester, Minn.

The Etiology and Pathogenesis of Alcoholic Cirrhosis of the Liver (Lantern Demonstration)

C. L. CONNOR, San Francisco

Regulation of the Serum Calcium Level During Pregnancy (Lantern Demonstration)

MEYER BODANSKY, Galveston, Texas

Studies on Hexyl Chloro-m-Cresol and Other Carbocyclic Antiseptics

F. W. HARTMAN and VICTOR SCHELLING, Detroit

Annual Variations in Seasonal Aspects of Mold Allergy. A Clinical and Atmospheric Study of Over Three Years (Lantern Demonstration)

SAMUEL M. FEINBERG, Chicago, and O. C. DURHAM, North Chicago, Ill.

Thursday, June 16—2 p. m.

SYMPOSIUM ON BLOOD DYSCRASIAS

A Symposium on Blood Dyscrasias Is Also Being Presented on Thursday Morning Before the Section on

Pharmacology and Therapeutics

Chairman's Address: Relation of Drug Therapy to Neutropenic States. ROY R. KRACKE, Emory University, Ga.

Experimental Production of Agranulocytosis in Dogs (Lantern Demonstration)

E. M. BUTT, Los Angeles

Leukemoid Reactions (Lantern Demonstration)

FRANK J. HECK, Rochester, Minn.

Red Cell Dimensions in Familial Hemolytic Anemia with Particular Reference to Atypical Cases (Lantern Demonstration)

JOSEPH M. HILL, Dallas, Texas

The Erythrocyte in Sick Cell Anemia (Lantern Demonstration)

L. W. DIGGS, Memphis, Tenn.

A Method for Differentiation of Blood Groups A₁ and A (Lantern Demonstration)

ISRAEL DAVIDSON, Chicago

The Gordon Test for Hodgkin's Disease. A Reaction to Eosinophils

JAMES B. McNAUGHT, San Francisco

Friday, June 17—2 p. m.

Election of Officers

Incidence of Primary Bronchogenic Carcinoma

PHILIP B. MATZ, Washington, D. C.

Primary Carcinoma of the Ureter

PAUL A. FERRIER and ALVIN G. FOORD, Pasadena, Calif.

Solid Ovarian Tumors (Lantern Demonstration)

HARRY C. SCHWEISSER, Memphis, Tenn.

Cytology of the Skin of Mice During Application of Carcinogenic Agents, Methylcholanthrene and Cholanthrene (Lantern Demonstration)

ROBERT C. PAGE, Tuckahoe, N. Y.

X-Ray Diffraction Analysis as Applied in Pneumococci (Lantern Demonstration)

HENRY C. SWEANY, Chicago

The Effects of Tuberculo-protein

A Quantitative Study (Lantern Demonstration)

HARRY J. CORPER, Denver

SECTION ON NERVOUS AND MENTAL DISEASES

MEETS IN ASSEMBLY HALL, EMPIRE HOTEL

OFFICERS OF SECTION

Chairman—SAMUEL D. INGHAM, Los Angeles

Vice Chairman—GROVES B. SMITH, Godfrey, Ill.

Secretary—PAUL C. BUCY, Chicago

Executive Committee—HANS H. F. REESE, Madison, Wis.,

HENRY R. VIETS, Boston, SAMUEL D. INGHAM, Los Angeles

Wednesday, June 15—9 a. m.

A dinner for the section will be held on Wednesday, June 15 at Louis' Fashion Restaurant

Marriage Among the Mentally Retarded (Lantern Demonstration)

L. H. ZIEGLER, Wauwatosa, Wis., and C. P. SHELTON, Boston

Discussion to be opened by DWIGHT L. WILBUR, San Francisco and LAWRENCE KOLB, Lexington, Ky.

The Psychoanalytic Treatment of Chronic Alcoholic Addiction in a Sanatorium (Lantern Demonstration)

ROBERT P. KNIGHT, Topeka, Kan.

Discussion to be opened by F. G. EBAUGH, Denver

Chairman's Address: Some Neurologic Aspects of Psychiatry

SAMUEL D. INGHAM, Los Angeles

A Follow-Up Report of a Human Being with Bilateral Frontal Lobectomy: Comparison with Cases of Unilateral Lobectomy (Lantern Demonstration)

RICHARD M. BRICKNER, New York

Discussion to be opened by W. F. SCHALLER, San Francisco

INSULIN SHOCK AND METRAZOL THERAPY

Clinical Observations and Results with Hypoglycemia and Convulsive Therapy in Schizophrenia (Lantern Demonstration)

HANS H. F. REESE, Madison, Wis.

Treatment of the Psychoses with Hypoglycemia and Induced Convulsions (Lantern Demonstration)

RICHARD H. YOUNG and G. ALEXANDER YOUNG, Omaha

Discussion to be opened by A. A. LOW, Chicago, and TITUS H. HARRIS, Galveston, Texas

Thursday, June 16—9 a. m.

The Cerebellum: A New Interpretation (Lantern Demonstration)

OLOF LARSELL, Portland, Ore.

Discussion to be opened by FREDERICK L. REICHERT and WEBB E. HAYMAKER, San Francisco

The Present Status of a Patient Who Has Had the Right Cerebral Hemisphere Removed (Motion Picture Demonstration)

K. G. McKEENZIE, Toronto, Canada

Discussion to be opened by MAX M. PFET, Ann Arbor, Mich., and HENRY R. VIETS, Boston

BRAIN TUMORS

Cerebral Pseudo-Tumor and Pseudo Abscess (Lantern Demonstration)

W. J. GARDNER, Cleveland

Discussion to be opened by HARRY WILKINS, Oklahoma City, and R. B. RANBY, Los Angeles

Intracranial Arteriovenous Varices with Brief Report of Ten Cases of Different Types and Special Reference to Treatment by Ligation (Lantern Demonstration)

R. E. SEYMERS, Memphis, Tenn.

Discussion to be opened by HALE A. HAVY, Seattle, and E. B. TOWNE, San Francisco

Tumors of the Fourth Ventricle (Lantern Demonstration)

W. MCK. CRAIG and J. W. KER. O'HAN, Rochester, Minn.

Brain Tumors in Infancy and Childhood

D. N. BUCHANAN and PERCIVAL BAILEY, Chicago

Discussion on papers of DRS. CRAIG and KER. O'HAN, and DRS. BUCHANAN and BAILEY to be opened by H. C. NAFFZIGER, San Francisco, and F. R. TEACH, Kansas City, Mo.

Friday, June 17—9 a. m.

Election of Officers

Horse Serum Neuritis (Lantern and Motion Picture Demonstration)

A. E. BRITTON, Philadelphia

Discussion to be opened by GEORGE WILSON, Philadelphia, and WALTER FFEEMA, Washington, D. C.

- The Treatment of Acute Infections of the Central Nervous System with Sulfanilamide (Lantern Demonstration)
JOSEPHINE B NEAL New York.
Discussion to be opened by R CANNON ELEY, Boston, and ARCHIBALD L HOYNE, Chicago
- Chronic Adhesive Spinal Arachnoiditis A Clinical and Pathologic Study (Lantern Demonstration)
R P MACKAY Chicago
Discussion to be opened by JOHN B DOYLE and J M NIELSEN, Los Angeles
- Epilepsy and the Carotid Sinus (Lantern Demonstration)
WILDER G PENFIELD and H M KEITH, Montreal Canada
Discussion to be opened by HENRY W WOLTMAN, Rochester, Minn
- Clinical Experiences with Diphenylhydantoin A New Anticonvulsant Drug (Lantern Demonstration)
H H MERRITT and T J PUTNAM, Boston
Discussion to be opened by EUGENE ZISKIND Los Angeles, and O P KIMBALL, Cleveland
- Results of Removal of Cerebral Cortical Scars
WILLIAM J GERMAN JR, New Haven Conn
Discussion to be opened by TEMPLE S FAY, Philadelphia, and R GLEN SPURLING Louisville, Ky

SECTION ON DERMATOLOGY AND SYPHILOLOGY

MEETS IN AUDITORIUM A, EMPIRE HOTEL

OFFICERS OF SECTION

- Chairman—JOSEPH V KLAUDER, Philadelphia
Vice Chairman—H J TEMPLETON, Oakland, Calif
Secretary—BEDFORD SHELMIER, Dallas, Texas
Executive Committee—HARRY R FOERSTER, Milwaukee, PAUL A O'LEARY, Rochester, Minn, JOSEPH V KLAUDER, Philadelphia

Wednesday, June 15—9 a m

SYMPOSIUM ON OCCUPATIONAL DERMATOSES

- Chairman's Address Erysipeloid as an Occupational Disease
JOSEPH V KLAUDER, Philadelphia
- Occupational Dermatoses An Educational Program (Lantern Demonstration)
C GUY LANE, Boston
- Incidence of Occupational Dermatoses and Their Causes in the Basic Industries
LOUIS SCHWARTZ, New York
- Industrial Dermatoses Remarks on Criteria for Diagnosis and on Future Immunologic Methods of Prophylaxis (Lantern Demonstration)
MARION B SULZBERGER, New York and CLARK W FINNERUD, Chicago
- The Practical Aspect of the Prevention of Industrial Dermatoses Elimination of Hazards and Protective Methods (Lantern Demonstration)
EARL D OSBORNE and JAMES W JORDON, Buffalo
- Analysis of Claims in Industrial Dermatoses
JOHN G DOWNING, Boston
- Some Medicolegal Aspects of Industrial Dermatoses
HARRY R FOERSTER Milwaukee
- Discussion on papers of Dr LANE, DR SCHWARTZ, DR SULZBERGER and FINNERUD, DR OSBORNE and JORDON, DR DOWNING and DR FOERSTER to be opened by C C DENNIE, Kansas City Mo, CLEVELAND J WHITE Chicago, and HIRSH E MILLER, San Francisco

Thursday, June 16—9 a m

- Are There Paradoxical Serum Reactions in Syphilis (Lantern Demonstration)?
REUBEN L KAHN Ann Arbor Mich
Discussion to be opened by FRDERICK G NOVY JR Oakland Calif
- The Present Status of Acetarsone Therapy in Prenatal Syphilis (Lantern Demonstration)
DONALD M PILLSBURY and H HARRIS PERLMAN Philadelphia
Discussion to be opened by JOSEPH YAMPOLSKY Atlanta Ga
- The Treatment of Congenital Syphilis with Mapharsen
JAMES K. HOWLES New Orleans
Discussion to be opened by JOHN E RAUSCHKOLB, Cleveland
- Acetarsone Orally in the Treatment of Acquired Syphilis in Adults
HARRY M ROBINSON and HARRY M ROBINSON JR Baltimore.
Discussion to be opened by CHARLES R REIN New York.

- High Antisyphilitic Level of Bismuth in the Blood Stream Method of Its Rapid Achievement and of Its Prolongation (Lantern Demonstration)
TORALD H SOLLMANN HAROLD N COLE, KATHARINE I HENDERSON, GARRETT A COOPER, W R LOVE and W F SCHWARTZ Cleveland
Discussion to be opened by GEORGE V KULCHAR, San Francisco
- Neurosyphilis in the Negro Spinal Fluid Manifestations in Untreated and Treated Cases (Lantern Demonstration)
SAMUEL GOLDBLATT, Cincinnati
Discussion to be opened by MARQUE O NELSON, Tulsa, Okla
- Treatment of Tabes Dorsalis Observations on Nine Hundred Patients (Lantern Demonstration)
PAUL A O'LEARY, Rochester Minn, JOSEPH EARLE MOORE, Baltimore, JOHN H STOKES, Philadelphia, UDO J WILE, Ann Arbor Mich, and THOMAS PARRAN, R A VONDERLEHR and LIDA J USILTON, Washington, D C
Discussion to be opened by WALTER FREEMAN, Washington D C

Friday, June 17—9 a m

Election of Officers

- Hydroadenitis Suppurativa (Verneuil) (Lantern Demonstration)
HENRY A BRUNSTING, Toledo, Ohio
Discussion to be opened by WILLIAM H GOECKERMAN, Los Angeles
- Tumor-like Keratoses Case Report (Lantern Demonstration)
DUNCAN O POTH, San Antonio, Texas
Discussion to be opened by H J TEMPLETON, Oakland, Calif
- Acne Urticata Polycythemia with Positive Oxidase Reaction in Sections and in Lesions in Situ (Lantern Demonstration)
FRED D WEIDMAN, Philadelphia
Discussion to be opened by J GARDNER HOPKINS, New York
- Cholesterol Studies and Low Fat Diet in Psoriasis (Lantern Demonstration)
JOHN F MADDEN, St Paul
Discussion to be opened by RICHARD J BAILEY, Spokane, Wash
- Sensitiveness of the Skin to X-Rays Following the Ingestion of Arsenic (Lantern Demonstration)
CARL W LAYTON and HARRY A CUMMING, Minneapolis
Discussion to be opened by W H GUY, Pittsburgh
- The Toxic Skin Manifestations Following Sulfanilamide Therapy (Lantern Demonstration)
J W TEDDER, New Orleans
Discussion to be opened by MARCUS R CARO, Chicago

SECTION ON PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH

MEETS IN CITY HEALTH BUILDING CIVIC CENTER

OFFICERS OF SECTION

- Chairman—ROBERT T LEGGE, Berkeley, Calif
Vice Chairman—CHARLES V CRASTER, Newark, N J
Secretary—I C RIGGIN, Richmond, Va

Discussion to be opened by J N BAKER, Montgomery, Ala

The Contribution of Mental Hygiene to Education on the Elementary Level

JAMES HOULOSE, Long Beach, Calif

Discussion to be opened by HERBERT R STOLZ, Oakland, Calif

Some Physiologic Concepts in Mental Hygiene

FORREST N ANDERSON, Los Angeles

SECTION ON UROLOGY

MEETS IN AUDITORIUM A EMPIRE HOTEL

OFFICERS OF SECTION

Chairman—ALBERT J SCHOLL, Los Angeles

Vice Chairman—GEORGE G REINLE, Oakland, Calif

Secretary—WILLIAM P HERBST, Washington D C

Executive Committee—JOHN H MORRISSEY, New York, HENRY W E WALTHER, New Orleans, ALBERT J SCHOLL, Los Angeles

Wednesday, June 15—2 p m

The Treatment of Testicular Deficiency with Testosterone Propionate (Lantern Demonstration)

E PERRY McCULLAGH, Cleveland

Criteria of Operability in Obstructive Lesions of the Bladder Outlet (Lantern Demonstration)

HAROLD C HABEIN, Rochester, Minn

The Treatment of Nongonococcal Infection of the Urinary Tract with Sulfamidamide

ANSON L CLARK, Oklahoma City

Resection of the Superior Hypogastric Plexus and the Sacral Sympathetic Ganglions for the Relief of Bladder Pain (Lantern and Motion Picture Demonstration)

C F SCHROEDER, Wyandotte, Mich, and R E CUMMING, Detroit

Advances in the Technic of Transurethral Prostatectomy (Motion Picture Demonstration)

REED M NESBIT, Ann Arbor, Mich

Prostatectomy or Transurethral Prostatic Resection (Lantern Demonstration)?

EDWIN DAVIS, Omaha

Vesical Diverticula (Lantern Demonstration)

ROBERT V DAY and HARRY W MARTIN, Los Angeles

Thursday, June 16—2 p m

The Significance of Roentgenographic Studies of the Urinary Tract During and After Pregnancy (Lantern Demonstration)

STANLEY R WOODRUFF, Jersey City, N J and ARTHUR H MILBERT, New York

Chairman's Address Urologic Conditions Resembling Chronic Glomerulonephritis (Motion Picture Demonstration)

ALBERT J SCHOLL, Los Angeles

The Treatment of Gonorrhea with Sulfamidamide (Lantern Demonstration)

BERNARD SILVER, Los Angeles

Surgical Procedures in the Treatment of Complications in Gonorrhea

JOHN H MORRISSEY, New York

Surgical Indications in Renal Tuberculosis (Lantern Demonstration)

JOHN L EMMETT and JOHN M KIBLER, Rochester, Minn

Cysts of the Kidney (Lantern Demonstration)

GEORGE W FISH, New York

Friday, June 17—2 p m

Election of Officers

Torsion of the Testicle

JOHN K ORMOND, Detroit

The Problem of Urinary Tract Absorption in Hydronephrosis

DUNCAN M MORISON, Edinburgh, Scotland

Testicular Tumors (Lantern Demonstration)

HUGH CABOT, Rochester, Minn

Surgery of Genito-Urinary Malignancy

HENRY G BUGBEE, New York

Radiation Therapy in the Treatment of Tumors of the Urinary Tract

CLYDE K EMERY, Los Angeles

The Visualization of the Adrenal Glands by Air Injection (Lantern Demonstration)

NORMAN W ROOME, Chicago

SECTION ON ORTHOPEDIC SURGERY

MEETS IN ASSEMBLY HALL, EMPIRE HOTEL

OFFICERS OF SECTION

Chairman—JOHN DUNLOP, Pasadena, Calif

Vice Chairman—OSCAR L MILLER, Charlotte, N C

Secretary—ROBERT V FUNSTEN, Charlottesville, Va

Executive Committee—ARTHUR T LEGG, Boston, FLEMING A CHANDLER, Chicago, JOHN DUNLOP, Pasadena, Calif

Wednesday, June 15—2 p m

Synovectomy of the Knee Joint for Chronic Arthritis (Lantern Demonstration)

GEORGE A L INGE, New York

Discussion to be opened by LORING T SWAIN, Boston,

and DAVID H KLING, Los Angeles

Spondylololthesis An Etiologic Factor in Backache (Lantern Demonstration)

HENRY W MEYERDING, Rochester, Minn

Discussion to be opened by SYLVAN L HAAS, San Francisco,

and CHARLES LEROY LOWMAN, Los Angeles

Treatment of Fracture-Dislocation of the Spine Associated with Cord Injury (Lantern Demonstration)

C C COLEMAN, Richmond, Va, and J M MEREDITH, University, Va

Discussion to be opened by FRIDERIC C BOST, San Francisco

and S C BALDWIN, Salt Lake City

Fractures of the Lower End of the Humerus (Lantern Demonstration)

GEORGE J GARCEAU, Indianapolis

Discussion to be opened by J H DORMAN, Dallas, Texas

and H W SPIERS, Los Angeles

Fascial Adhesions in Low Back Pain and Arthritis (Lantern Demonstration)

CHARLES MURRAY GRATZ, New York

Discussion to be opened by ARTHUR STEINBERG, Iowa City,

and HULFET J WICKOFF, Seattle

Newer Concepts and Methods of Teaching Orthopedic Surgery (Lantern and Motion Picture Demonstration)

PHILIP LEWIS, Chicago

Thursday, June 16—2 p m

Factors to be Considered in Bone Metabolism with Suggestion as to the Clinical Value of Vitamin D and Parathyroid Extract (Lantern Demonstration)

CHARLES F NELSON, Beverly Hills, Calif

Discussion to be opened by EDWARD L COMBER, Chicago

and WALTER BAUER, Boston

Relation Between Birth Injuries and the Obstetric History (Lantern Demonstration)

STEFFE F STEWART, Los Angeles

Discussion to be opened by OSCAR L MILLER, Charlotte, N C

and CHARLES E SPYFI, Denver

Chairman's Address Transcondylar Fractures of the Humerus in Childhood (Lantern Demonstration)

JOHN DE LOE, Pasadena, Calif

The Use of Absorbable Metal in Bone Surgery (Lantern Demonstration)

EARL D McPHER, Oklahoma City

Discussion to be opened by CHARLES SCOTT, Ft. Worth, Texas,

and ROGER A NELSON, Seattle

Dashboard Fractures of the Patella (Motion Picture Demonstration)
C FRED FERCIOT, Lincoln Neb
Discussion to be opened by W B CAPRELL, Dallas Texas,
and LOUIE FELGER, Los Angeles

Friday, June 17—2 p m

Election of Officers

Common Sense in the Treatment of Acute Hematogenous Osteomyelitis (Lantern Demonstration)

J ALBERT KEY St Louis
Discussion to be opened by W D GRIESEMER, Reading, Pa, and JESSE T NICHOLSON Philadelphia

A Method of Reduction of Fractured Neck of the Femur by Transtrochanteric Skeletal Traction to be Followed by Axial Fixation with Threaded Steel Pins, with a Report of Five Years Follow Up on Transcervical Fixation (Lantern Demonstration) DAVID R TELSON Brooklyn
Discussion to be opened by ROLAND HAMMOND Providence R I and LEROY C ABBOTT, San Francisco

Time Element in Fractures (Lantern Demonstration)

BARNEY J HEIN Toledo Ohio
Discussion to be opened by DONALD C DURMAN Saginaw Mich, E M PORTER Great Falls, Mont, and G MASSER TAYLOR Los Angeles

Estimation of Disability After Injury (Lantern Demonstration)

WALTER G STERN Cleveland
Discussion to be opened by HARRY E MOCK Chicago
EARL D MCBRIDE, Oklahoma City and LIONEL D PRINCE and HOWARD W FLEMING San Francisco

The Operative Treatment of Pes Planus (Lantern Demonstration)

CHARLES S YOUNG, Los Angeles
Discussion to be opened by REX L DINELEY Kansas City, Mo and HENRY W WILSON, Denver

SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

MEETS IN CITY HEALTH BUILDING, CIVIC CENTER

OFFICERS OF SECTION

Chairman—HENRY L BOCKUS Philadelphia
Vice Chairman—DESCUM C MCKENNEY Buffalo
Secretary—A H AARON, Buffalo
Executive Committee—ERNEST H GAITHER Baltimore Louis
A BLUE, Rochester, Minn, HENRY L BOCKUS Philadelphia
The annual banquet of the section will be held on Wednesday, June 15, 7 p m at the Hotel St Francis

Wednesday, June 15—9 a m

Gastroenterology in the Practice of Cardiology (Lantern Demonstration)

LOUIS F BISHOP JR New York
Discussion to be opened by JOHN R TWISS New York
The Effect of Smoking on the Activities of the Alimentary Tract (Lantern Demonstration)

ANDREW C ILY Chicago
Discussion to be opened by SIDNEY A PORTIS Chicago
Gallbladder Infection, Its Experimental Production and Attempts at Specific Therapy

MARTIN E REHRSS and GUY M NELSON Philadelphia
Discussion to be opened by GARRETT CHENEY San Francisco

Operative Injury to the Anal Sphincter Mechanism (Lantern Demonstration)

PALL C BLAISDELL Pasadena Calif
Discussion to be opened by MALCOLM R HILL Los Angeles

Proctologic Tumors Diagnostic Difficulties and Pathologic Changes (Lantern Demonstration)

CLAUDE C TUCKER and C ALEXANDER HELLWIG Wichita Kan

Discussion to be opened by CURTICE ROSSER Dallas Texas

Recording the Movements of the Gastrointestinal Tract by Roentgen Kymography (Motion Picture Demonstration)

WENDELL G SCOTT St Louis
Discussion to be opened by CHARLES W DUDEN St Louis

Medical Aspect of Cancer of the Stomach (Lantern Demonstration)

Discussion to be opened by MANUEL FELIX CUNHA San Francisco

Gastrointestinal Symptoms in Disease of the Brain (Lantern Demonstration)

HARRY GAUSS Denver
Discussion to be opened by EDWARD G BILLINGS Denver

Thursday, June 16—9 a m

Chairman's Address Training of the Gastroenterologic Internist

HENRY L BOCKUS Philadelphia

SYMPOSIUM ON ULCERATIVE COLITIS

The Medical Management of Chronic Ulcerative Colitis (Lantern Demonstration) THOMAS T MACKIE, New York
Functional or Sociologic Disorders of the Colon Medical and Surgical Considerations (Lantern Demonstration)
ELMER G WAKEFIELD and CHARLES W MAYO Rochester, Minn

The Surgical Treatment of Ulcerative Colitis

THOMAS E JONES Cleveland
Prognosis of Ulcerative Colitis (Lantern Demonstration)

JOHN H WILLARD Philadelphia, J F PESSLE, Trenton, N J and J WARREN HUNDLEY, Philadelphia

Discussion on papers of DR MACKIE, DRs WAKEFIELD and MAYO, DR JONES and DRs WILLARD, PESSLE and HUNDLEY to be opened by WILLIAM FITCH CHENEY, San Francisco JOHN H FITZGIBBON, Portland, Ore, WILLIAM C BOECK, Los Angeles, and ARTHUR L BLOOMFIELD, San Francisco

Studies on Treatment in Intestinal Tuberculosis (Lantern Demonstration)

LEO L HARDT and JOHN S COLLIER Chicago
Discussion to be opened by DESCUM C MCKENNEY, Buffalo

A Review of a Group of Proctologic Operations Using Spinocurin as an Anesthetic (Lantern Demonstration)

MARTIN S KLECKNER Allentown, Pa
Discussion to be opened by DUDLEY A SMITH, San Francisco

Intravenous Alimentation with Special Reference to Protein (Amino Acid) Metabolism (Lantern Demonstration)

ROBERT ELMAN St Louis
Discussion to be opened by ANDREW C ILY, Chicago

Friday, June 17—9 a m

Election of Officers

Clinical Observations on a Group of Ulcer Cases (Lantern Demonstration) J McDONALD WILLIAMS, Elgin, Ill
Discussion to be opened by GRANT H LANPHERE, Los Angeles, and FRED H KRUSE San Francisco

The Value of Roentgenologic Demonstration of the Crater in Duodenal Ulcer (Lantern Demonstration)

FREDERIC E TEMPLETON and A W MARCOWITZ, Chicago
Discussion to be opened by THEODORE L ALTHAUS, San Francisco

Sex Hormones in Peptic Ulcer (Lantern Demonstration)

DAVID I SANDWEISS Detroit
Discussion to be opened by WARREN O NELSON, Detroit

Gastritis Correlation of Gastric Analysis and Clinical Observations with Gastroscopy

JOSEPH BANK Phoenix, Ariz, and ROBY JOHN F RENSCHAW Los Angeles

Discussion to be opened by FRANK D GORHAM, St Louis

Gastroscopy as Compared with Other Methods of Diagnosis in Gastric Lesions (Lantern Demonstration)

ELMER B FREEMAN, Baltimore
Discussion to be opened by ROBY JOHN F RENSCHAW, Los Angeles

Some Forms of Hepatitis Not Commonly Recognized (Lantern Demonstration)

JAMES F WHEE Rochester Minn
Discussion to be opened by DWIGHT L WILBUR, San Francisco

Strongyloidosis A Discussion of Strongyloid Infestation with Emphasis on Its Therapy

VIRGIL E SIMMONS Louisville, Ky
Discussion to be opened by THOMAS T MACKIE, New York

Extrahepatic Metastatic Growths from Upper Abdominal Malignant Neoplasms Report of Twelve Cases (Lantern Demonstration)

HARRY E BACON Philadelphia
Discussion to be opened by NEWTON D SMITH Rochester, Minn and W H DANFORTH Los Angeles

SECTION ON RADIOLOGY

MEETS IN LOFT OF OLIVE HOUSE, CIVIC CENTER

OFFICERS OF SECTION

Chairman—B R KIRKLIN Rochester Minn
Vice Chairman—R G TAYLOR Los Angeles
Secretary—JOHN T MURPHY Toledo Ohio
Executive Committee—EDWARD L JR Chicago
ROBERT GOLDEN New York B K KAPLAN Rochester, Minn

Wednesday, June 15—9 a m

The Thymus Studies of Some Changes in the Gonads and Pituitary Following Destruction of the Thymus by Roentgen Irradiation (Lantern Demonstration)
JACOB GERSHON-COHEN, HARRY SHAY, S S FELS, DAVID R MERANZE and THEODORE MERANZE, Philadelphia
Factors Influencing the Radiosensitivity of Malignant Neoplasms of the Uterine Cervix (Lantern Demonstration)
H H BOWING and ROBERT E FRICKE Rochester Minn
The Irradiation of Kidney Tumors in Children (Lantern Demonstration)
H D KERR, Iowa City
Apical Lung Tumors (Lantern Demonstration)

JUSTIN J STEIN, Hines Ill
Supervoltage Roentgen Treatment of Carcinoma of the Bladder (Lantern Demonstration)

RICHARD DRESSER and ROGER C GRAVES, Boston
The Roentgen Treatment of Acute Peritonitis and Other Infections with Mobile Apparatus (Lantern Demonstration)
JAMES F KELLY and D ARNOLD DOWELL, Omaha

Thursday, June 16—9 a m

JOINT MEETING WITH SECTION ON PEDIATRICS IN AUDITORIUM OF OPERA HOUSE CIVIC CENTER

Sinus Disease in Children (Lantern Demonstration)

W WALTER WASSON, Denver
Sinus Treatment in Children (Lantern Demonstration)

EDWARD C MITCHELL Memphis Tenn
Ephedrine in a Physiologic Vehicle and Lateral Head Low Posture in Treatment of the Nose and Sinuses (Lantern and Motion Picture Demonstration)

SIDNEY N PARKINSON, Oakland Calif

Discussion to be opened by JOHN J SHEA, Memphis, Tenn

Diagnosis and Treatment of Thymus Disease with X-Rays (Lantern Demonstration)

CLAUDE K HASLEY, Detroit
Experimental Phases of the Thymus Problem (Lantern and Motion Picture Demonstration)

L G ROWNTREE and N H EINHORN, Philadelphia
Thymus Problem in Children (Lantern Demonstration)

A GRAHAM MITCHELL Cincinnati
Discussion to be opened by EDITH BOYD Minneapolis

Friday, June 17—9 a m**Election of Officers**

Chairman's Address Lipoid Pneumonitis (Lantern Demonstration)
B R KIRKLY, Rochester Minn

Planigraphy Its Application to Thoracic Diagnosis (Lantern Demonstration)
WILLIAM E HOWES, Brooklyn

Body Section Radiography in Surgical Conditions (Lantern Demonstration)
SHERWOOD MOORE, St Louis

Hydronephrosis Caused by Aberrant Renal Blood Vessels Demonstrated by Intravenous Urography (Lantern Demonstration)
JACOB ABOWITZ, Los Angeles

Further Observations of the X-Ray Manifestations of Amebic Infections of the Large Bowel (Lantern Demonstration)
J C BELL, Louisville Ky

Epiphysitis of the Capitellum of the Humerus (Lantern Demonstration)
JOSEPH F EDWARD, Washington, D C

Gastrocolic Fistulas (Lantern Demonstration)
WILBUR P BAILEY, Los Angeles

THE SCIENTIFIC EXHIBIT**THE SCIENTIFIC EXHIBIT**

The Scientific Exhibit is correlated with the Scientific Assembly as far as possible. Each section of the Scientific Assembly has appointed a section representative or a committee to the Scientific Exhibit. In addition to 155 exhibits, the Board of Trustees has provided for special exhibits on Anesthesia and on Fractures.

All exhibits are open to awards except the special exhibits and the organization exhibits of the American Medical Association headquarters group.

The Scientific Exhibit is located in the Civic Auditorium in Polk Hall and the adjoining corridors with entrances from the Technical Exhibit. Admission to the Scientific Exhibit is limited to Fellows and guests of the Association who have registered for the session and who are wearing badges or holding guest cards. The Scientific Exhibit is not open to the public.

SPECIAL EXHIBIT ON ANESTHESIA

The special exhibit on anesthesia is presented for the second year under the auspices of an exhibit committee appointed by the Committee on Scientific Exhibit of the Board of Trustees as follows: P J Hanzlik, San Francisco, Chauncey D Leake, San Francisco, Philip D Woodbridge, Boston, Ralph M Waters, chairman, Madison, Wis.

The 1938 exhibit will deal with the following subjects:

Premedication agents

Local anesthesia

General anesthesia

A pamphlet has been prepared for distribution at the exhibit. Demonstrations will be given continuously throughout the week by a competent corps of anesthetists.

SPECIAL EXHIBIT ON FRACTURES

The exhibit on fractures is continued again this year along somewhat the same lines as last year. The special exhibit committee appointed by the Committee on Scientific Exhibit of the Board of Trustees is composed of the following: Frank D Dickson, Kansas City, Mo., Walter Estell Lee, Philadelphia, Kellogg Speed, chairman, Chicago.

The following subjects will be considered:

- 1 Plaster of Paris Making and Storing
- 2 Application of Plaster of Paris
- 3 Fracture of the Lower End of the Radius
- 4 Fracture of the Spine—Compression

5 Fracture of the Ankle**6 First Aid Treatment of Fractures of the Lower Extremities**

Demonstrations will be given continuously throughout the week. A special folder has been prepared for distribution in connection with the exhibit.

The following physicians will take part in the demonstration:

Otis F Akin, Portland, Ore.

Harold D Barnard, Los Angeles, Calif.

Leonard Barnard, Oakland, Calif.

Walter Birnbaum, San Francisco, Calif.

Joseph H Boyes, San Francisco, Calif.

L S Cherney, San Francisco, Calif.

Albert G Clark, San Francisco, Calif.

Dwight F Clark, Evanston, Ill.

E W Cleary, San Francisco, Calif.

John W Cline, San Francisco, Calif.

F E Clough, San Bernardino, Calif.

Wilbur J Cox, San Francisco, Calif.

Martin W Debenham, San Francisco, Calif.

R L Dresel, San Jose, Calif.

Charles A Dukes, Oakland, Calif.

Donald C Durnan, Saginaw, Mich.

C Fred Ferriest, Lincoln, Neb.

Charles B Fowler, Oakland, Calif.

Alfred E Gallant, Los Angeles, Calif.

W W Greene, San Francisco, Calif.

J M Greer, Phoenix, Ariz.

Delbert Hand, San Francisco, Calif.

Nelson J Howard, San Francisco, Calif.

Russell F Jackle, San Francisco, Calif.

Joseph Jephson, San Jose, Calif.

J Joutzenheier, San Francisco, Calif.

G J McChesney, San Francisco, Calif.

H H Marble, San Francisco, Calif.

Carleton Mathewson Jr, San Francisco, Calif.

J Minton Meherin, San Francisco, Calif.

Merrill Mensor, San Francisco, Calif.

Arthur R Metz, Chicago, Ill.

Jesse Nicholson, Philadelphia, Pa.

Norman C Paine, Mendocino, Calif.

E Payne Palmer, Phoenix, Ariz.

R S Palmer, Pomona, Calif.

Leon O Parker, San Francisco, Calif.

Edward K Irigge, Los Angeles, Calif.

Lionel D Prince, San Francisco, Calif.

Paul A Quantance, Los Angeles, Calif.

S B Richard, San Bernardino, Calif.

Edward S Rutli, Los Angeles, Calif.

George Sanderson, Stockton, Calif.

H I Schott, Los Angeles, Calif.

A B Sirbu, San Francisco, Calif.

Emuel D Smith, Milwaukee, Wis.

H W Spiers, Los Angeles, Calif.

P P Stephen, Oakland, Calif.

Philip Stephens, Los Angeles, Calif.

Steele Stewart, Los Angeles, Calif.

Walter Stuel, San Antonio, Texas.

C S Venable, San Antonio, Texas.

I M Walker, Los Angeles, Calif.

James P Warren, San Francisco, Calif.

George Waters, San Francisco, Calif.

H W Wile, Denver, Colo.

Charles S Young, Los Angeles, Calif.

C L Young, Los Angeles, Calif.

Section on Practice of Medicine

The representative to the Scientific Exhibit from the Section on Practice of Medicine is Fred M Smith, Los Angeles.

ELLIOTT P JOSEPH, LOUIS I DUBOIS, HOWARD I ROSE and HEIDBERT H MARKS, Boston and New York.

Advances in the Treatment of Diabetic Mellitus. Exhibit showing recent trends in the incidence of diabetes in various

population groups the changing incidence of complications of the disease, resulting from the increasing duration of life of diabetic patients, and the problems of treatment presented, new data on the diagnosis, etiology and pathology of the disease and on the results of treatment with protamine insulin, relation of the anterior pituitary and diabetes as demonstrated experimentally and by a comparison of acromegaly and diabetes advances in the treatment of diabetes and the further progress that can be achieved by intensive application of information of the disease and of up-to-date therapeutic methods

STACY R. METTIER and CHARLES L. CONNOR, University of California Hospital, Medical Center San Francisco

Structural Changes of the Bone Marrow in Various Hematologic States Exhibit consisting of microscopic specimens of fixed tissue and of coverslip smears abstract of case histories and important laboratory observations, water color paintings of bone marrow smears, diagrams of aleukemic leukemia, specimens of multiple myeloma, plasmacytoma, purpura haemorrhagica pernicious anemia aplastic anemia and the bone marrow during the course of infections and other conditions

WILLARD O. THOMPSON and MORRIS J. HECKEL, Chicago

The Production of Genital Growth in the Male Exhibit demonstrating that the anterior pituitary-like principle from the urine of pregnant women exerts a powerful stimulus to the growth of the genitalia of the human male, series of photographs showing marked genital growth from its use before and after the age of puberty, notably in patients with hypogonadism and undescended testes, stages in the production of premature puberty following its administration, treatment of hypogonadism and undescended testes, importance of avoiding marked genital growth in young boys

R. J. REITZEL, S. P. LUCIA, Department of Medicine and KARL F. MEYER Hooper Foundation for Medical Research, University of California Medical School San Francisco

Clinical and Epidemiologic Demonstration of Various Infectious Diseases Exhibit of clinical data characteristic temperature charts, case summaries, laboratory diagnostic methods of pneumonia, gonococcal infections meningitis brucellosis tularemia, plague, Weil's disease, rat-bite fever relapsing fever, psittacosis venereal lymphogranuloma trichinosis and other infectious diseases, presentation with charts and models showing heterogeneous infection chains of such diseases as tularemia brucellosis, relapsing fever, trichinosis sylvatic plague and psittacosis Exhibit includes a model typing station for pneumonia

EDWARD F. HARTUNG, JOHN D. CURRENCE and MARGARET STRAUSS NEIL, New York Post-Graduate Medical School and Hospital, New York

Social Aspects of Chronic Rheumatism Exhibit showing the extent of the morbidity of rheumatic diseases in the United States, the long duration of disability, and the economic and industrial loss, the almost total lack of hospital facilities to combat this problem, and a plan of hospitalization which will definitely cut down the incidence of chronic disability due to rheumatism

RUSSELL L. CECIL New York New York State Department of Health, and Metropolitan Life Insurance Company

New Methods for Pneumonia Control Exhibit of charts, maps and specimens covering (a) modern methods for pneumococcus pneumonia diagnosis treatment and recent experience with serum treatment (b) survey of pneumonia incidence in United States and Canada, (c) outline of the New York State Department of Health program for pneumonia control

W. A. SODEMAN and G. E. BURCH, Tulane University School of Medicine New Orleans

Tissue Pressure and Skin Distensibility, Objective Measurements in Vascular States Exhibit showing apparatus and methods for the determination of tissue pressure and skin distensibility with the accumulated data, charts exhibiting the application of these data to the interpretation of the normal and abnormal physiology of interchange of fluid between blood and tissue spaces, relationship of the factors to an

understanding of the limitation of the degree of cardiac and other types of edema, demonstration of the use of these methods in the diagnosis, prognosis and evaluation of therapy in scleroderma

AUGUST A. WERNER, St. Louis University Medical School, St. Louis

Theilm Clinical Studies Exhibit showing the results of clinical research with castrate women and the effects on the endometrium and vaginal tissue, presentation of the syndrome accompanying castration, ovarian hypofunction menopause and involutional melancholia with treatment

MERRITT B. WHITTEK, Dallas

Electrocardiogram with Midaxillary Leads Exhibit illustrating the manner of application of the electrodes in taking midaxillary leads, enlarged reproductions from actual electrocardiograms comparing the midaxillary leads with the conventional limb leads in various cardiac disorders and demonstrating certain advantages of the former leads over the latter, observations demonstrating that in anteriorly located myocardial infarction and in predominant left ventricular strain (as in hypertension and other conditions) the midaxillary leads often show the characteristic electrocardiographic changes of these lesions earlier and to a more marked degree and these changes often persist longer than similar changes seen in the conventional limb leads of the electrocardiogram, apparent advantages of the midaxillary leads in multiple infarctions, interventricular conduction disturbances, pericarditis, and so on, as well as the characteristic changes from digitalis

BAYARD T. HORTON, CHARLES SHEARD and MARVIN M. D. WILLIAMS Mayo Clinic, Rochester, Minn

Isomotor Regulation of the Temperatures of the Extremities in Health and Disease Exhibit of charts and diagrams showing the results of physiologic and clinical investigations concerning (1) surveys of skin temperatures of various portions of the body, (2) degree of vasoconstriction as evidenced in the effects produced on skin temperatures by changes of environmental conditions, (3) effects of ingestion of food on the temperatures of the extremities, (4) relative roles of upper and lower extremities in the regulation of loss of heat from the body in environments ranging from 60 to 95 F, (5) comparison of results obtained on normal individuals with observations on subjects with peripheral vascular diseases

E. KOST SHELTON, BENJAMIN A. TAGER and SHELDON A. PAXNE Los Angeles

Endocrine Factors in Growth and Development Exhibit of special photographs of children with endocrine disturbances taken in the nude against a black background marked off in six inch squares, allowing accurate comparison of changes taking place during period of treatment

Section on Surgery, General and Abdominal

The representative to the Scientific Exhibit from the Section on Surgery General and Abdominal, is Grover C. Penberthy, Detroit. In addition to the several exhibits there will be a continuous motion picture program in an adjoining area

CONRAD R. LAM, Henry Ford Hospital, Detroit

Experiments on Intra-Abdominal Pressure Role of distention in atelectasis and postoperative pneumonia Exhibit of diagrams of apparatus, enlarged reproductions of kymograph records photographs of pathologic specimens, photomicrographs tables and transparencies showing the effect of variations in abdominal pressure on respiration and blood pressure and the influence of increased abdominal tension on the development of postoperative pulmonary complications

SHERWOOD MOORE St. Louis

Body Section Radiograph Exhibit of collection of roentgenograms of conventional type compared with body section roentgenograms or laminagrams of the same subject illustrating the advantages of the latter in certain pathologic conditions certain clinical facts, and, where possible photographic reproductions of pathologic specimens in pulmonary disease and tuberculosis of bone illustrating the practical utility of body section radiography in surgical lesions

A C SCOTT Scott and White Hospital, Temple Texas

Mammary Tumors Diagnosis and Treatment Exhibit of moulages charts and other data dealing with technic for diagnosis of breast tumors demonstrated by series of moulaged breasts and sagittal breast sections showing early dimpling on the skin surface by shadow test, the radical excision of breast tumors shown in each succeeding step by a series of moulages motion pictures in color demonstrating the shadow test and the radical excision as done with the loop-cantery knife

WILLIAM OSLER ABBOTT, University of Pennsylvania, Philadelphia and CHARLES G JOHNSTON, R J NOER GROVER C PLEBERTH, J C KEATING and J E LOFSTROM, Wayne University College of Medicine Detroit

Acute Intestinal Obstruction—Treatment by Small Intestinal Intubation Exhibit of charts showing clinical histories of patients with intestinal obstruction, photographs of roentgenograms before and after treatment and of roentgenograms indicating the nature and location of the lesions, kymographic tracings of the activity of obstructed intestine and drawings of diseased intestine Moving picture film depicting technic of treatment

HAROLD BRUNN and Associates, The Thoracic Clinic, University of California Hospital, San Francisco

Surgical Conditions of the Thorax Exhibit of roentgenograms, charts and models of various surgical conditions of the chest including bronchiectasis, tumors hydatid cysts and others and operation on the heart, and motion pictures

HARRY C SALTZSTEIN EDWARD H LALPPE and M Z FELDSTEIN, Detroit

The Care of Advanced Cancer Exhibit dealing with the clinical course of terminal cancer with analysis of the terminal symptoms of patients who died of cancer differences in terminal manifestations and clinical mode of exitus of cancer in different regions of the body, average length of terminal care necessary compared to incidence of these cases in general hospitals and United States mortality figures the treatment of far advanced cancer, with a discussion of palliative operations palliative roentgen treatment general measures and nursing care for advanced cases, and pain relief, showing drugs with comparison of different narcotics and measures to combat morphine addiction, nerve injections, subarachnoid alcohol injections with review of literature technic (illustrated with diagrams), indications complications and results

MANUEL GRODINSKY and EDWARD HOLYOKE Department of Anatomy and Surgery, University of Nebraska College of Medicine Omaha

Fasciae and Fascial Spaces of the Head, Neck and Adjacent Regions and Their Relation to Infections Exhibit consists of (1) transparencies, four of which are made from diagrammatic drawings derived from dissections injections, and sections of human material, and the remainder made from tracings on bleached photographs of sections of adult and fetal material (2) moulages made from transverse sections of adult material

GORDON B NEW F A FIGI, F Z HAYENS and J B ERICH, Mayo Clinic, Rochester Minn

Deformities of the Face, Correction by Plastic Surgery Exhibit of models photographs and motion pictures showing the technic of various types of operations for correcting acquired and congenital deformities of the face, the appearance of the patient before and after operation by means of numerous casts and photographs Subjects treated include (1) harelip (2) rhinoplasty (3) deformities resulting from automobile injuries, (4) various types of deformities of the nose mandible and ear (5) use of tubed flap for closing perforations of the cheek resulting from cancer, (6) angiomas and scarring due to burns

GEORGE W SWIFT and S N BERENS Seattle

Cerebrocranial Injuries Exhibit of specimens mounted in glass showing the different types of injuries to the brain cortex, brain stem and ventricles post-traumatic atrophies charts showing the different types of injuries with mortality statistics, charts showing actual brain injuries with photographs, charts showing microscopic sections of concussions

of the brain, charts showing post traumatic sequelae with encephalograms, charts outlining treatment for the three stages (a) shock, (b) brain injuries, (c) sequelae, statistical charts showing a series of head injuries

EUGENE B POTTER and P A ROHFER, The Mason Clinic, Seattle

Pararenal Tumors Exhibit showing case reports of large pararenal tumors, with roentgenograms, gross mounted specimens and microscopic pathologic study, charts with classification of pararenal tumors charts referable to surgical technic

R RUSSELL BEST and N FREDERICK HICKEN, Omaha

A Nonoperative Method for Removal of Residual Biliary or Common Duct Stones Exhibit showing that stones mucous plugs, blood clots or clumps of inspissated bile are not infrequently present in the common duct following operations on the biliary tract and that their presence may be suggested by some sign or symptom or may be proved by cholangiography if a T-tube or catheter is present or a biliary fistula exist presentation of a method of forcing out the smaller foreign bodies by simultaneously increasing the pressure behind them and completely relaxing the sphincter of Oddi by various means the increased intraductal pressure and flushing out effect is obtained by administering dehydrocholic acid, if a tube or fistula is present, direct irrigation with warm physiologic solution of sodium chloride olive oil or iodized oil in addition to the dehydrocholic acid enables one to increase the intraductal pressure, charts reveal the increase of intraductal pressure by the administration of dehydrocholic acid Roentgenograms show that foreign bodies in the common duct can be dislodged by the method described indications and contraindications are presented the operative removal of common duct stones is illustrated

JOHN O BOWER JOHN C BLISS and H A K MANGIE Philadelphia

Comparative Study of the Reparative Processes in the Gastrointestinal Mucosa Following Division and Suture with Special Reference to Very Fine Catgut Sutures Exhibit of transparencies showing the results of suture of the divided mucous membrane of the dog's stomach and intestine photo micrographs showing tissue reaction and comparative rate of absorption of coarse and fine catgut at twenty four hour intervals after operation, gross and transparent specimens showing arterial supply of the stomach of man and dog motion pictures in color showing the technic of various types of gastric resection with special reference to the use of 50 chromic catgut

HAROLD LINCOLN THOMPSON, Los Angeles

Acute Perforation of Peptic Ulcer Exhibit of charts, diagrams drawings, photographs surgical and pathologic specimens and roentgenograms illustrating the etiology symptom diagnosis pathology treatment and results of treatment of acute perforation of gastric, duodenal and gastroyejunal ulcers

JOEL W BAKER and MAURICE F DWYER, The Mason Clinic Seattle

Results in the Surgical Treatment of Duodenal Ulcer Exhibit of photographs of correlated preoperative and post operative roentgenograms and resected specimens roentgenologic function and apparent (false) dysfunction from one to two weeks after operation indications for surgery in duodenal ulcer individual indications for the various surgical procedures used in duodenal ulcers mounted specimens, illustrating hemorrhagic and perforating ulcers

BERNHARD STEINBERG Toledo Hospital Toledo Ohio

Protection Against Peritonitis Exhibit demonstrating tissue reaction together with the changing picture of the peritoneal exudate throughout the course of diffuse experimental peritonitis peritoneal exudate correlated with the peripheral blood and the general condition of the cardiovascular system exemplified by electrocardiographic tracings and continuous blood pressure throughout the entire course of peritonitis pictures of preventive and curative treatment drawn from the anatomy and abnormal physiologic changes observed during the experiment

ments suggestive therapeutic measures, both preventive and curative

ALBERT D DAVIS, San Francisco

Plastic Surgery Exhibit of photographs showing patients prior to operation, operative steps, appearance during reconstructive surgery, and postoperative results

ELIN L PEARL, San Francisco

Muscle Splitting Extraperitoneal Lumbar Ganglionectomy, A Satisfactory Approach to the Retroperitoneal Space Motion picture demonstration in color of the operation of lumbar ganglionectomy, performed by a completely muscle-splitting extraperitoneal approach, interesting anatomic landmarks, indicating the use of the same approach for extraperitoneal exposure of the great abdominal vessels, ureter, psoas muscle and vertebrae

DUDLEY SMITH, San Francisco

Management of Colostomy Motion picture demonstration in color showing the details of colostomy care and the technic used to insure comfort, cleanliness and freedom from odor patients engaged in various professional, business and industrial occupations and others enjoying the usual social diversions and sports, "social isolation" of colostomy patients shown to be due to ignorance of the details of proper care

Section on Obstetrics and Gynecology

The representative to the Scientific Exhibit from the Section on Obstetrics and Gynecology is H Close Hesseltine, Chicago. Motion pictures will be shown under the auspices of the section in an area adjoining the exhibit

JOHN C RUDDOCK and ROBERT B HOPE, University of Southern California, Los Angeles

Peritoneoscopy Exhibit of diagrams, pictures, tables, charts and posters describing technic for visualization of abdominal cavity, hazards of the procedure and how avoided, method of obtaining biopsies, special techniques for stomach examination division of adhesions, analysis of cases showing pathologic conditions encountered and evaluation of the procedure

L H GARLAND and A V PETTIT, San Francisco

Prediction of Certain Types of Difficult Labor by Pelvicography An Obstetric and Radiologic Investigation Exhibit of a series of transparencies illustrating the basic principles of the roentgen diagnosis of the various morphologic types of female pelvis together with adequate text and tabular information, the four main types of female pelvis are illustrated and the exact clinical significance of these various types in a series of 300 carefully studied cases is outlined

RICHARD TORPIN, University of Georgia School of Medicine Augusta

Placental Site Studies Using an Original Method of Amniotic Sac Distention Exhibit of (1) paraphernalia used (2) fresh placental sac distended in a tank of fluid showing the cervical opening and two opposite bulges located at the site of the uterine horns (3) clay models of distended sacs showing location outline and approximate size of the placenta and the character of the placental margin whether normal, marginal or circumvallate

CHARLES EDWIN GALLOWAY and TOM D PAUL, Evanston Ill

The Cervix and Colored Microphotography Exhibit demonstrating the use of colored photographs for teaching purposes as well as for records, the camera a model of the female pelvis and black speculum in place shadow boxes with colored slides projector with a small screen

JULIAN M BRUNER, Des Moines and L F ROEBROOK, Ames, Iowa

Photographic Records of the Cervix Uteri Exhibit demonstrating a method of making photographic records of the cervix uteri. Photographs illustrating lesions of the cervix special speculum required for this work illustrated by drawings method described in detail whereby the gynecologist can make photographic records of the cervix in the office

FRED L ADAIR and EDITH J POTTER, Chicago

Causes of Death in the Fetal and Neonatal Period Exhibit of photographs drawings, roentgenograms and diagrams showing causes of death divided into six groups—anoemia, trauma, infections malformations, idiopathic diseases, prematurity, each of which is subdivided into principal maternal conditions causing or associated with each group, and the pathologic conditions produced in the fetus or infant as anoemia—placenta praevia, abruptio placentae and cord abnormalities, producing petechial hemorrhages, aspiration of amniotic fluid depression of respiratory center and so on in the fetus and infant

In an area adjoining the exhibit of the section, motion pictures on obstetrics and gynecology will be shown on a definite schedule throughout the week

E D PLASS, Iowa City, Delineary

J B DE LEE, Chicago, *Treatment of Asphyxia Neonatorum*

H O JONES, Chicago, *Subtotal Abdominal Hysterectomy*

F L ADAIR, Chicago, *Colpoclysis*

Section on Ophthalmology

The section exhibit committee of the Section on Ophthalmology consists of Georgiana Dvorak-Theobald Oak Park, Ill, chairman Dohrmann K Pischel, San Francisco, and Derrick T Vail Jr, Cincinnati. A motion picture program will be conducted continuously throughout the week in an area adjoining the exhibits

JOHN E L KEES and HARRY GOLDBLATT, Institute of Pathology, Western Reserve University, Cleveland

Vascular Changes in the Eyes in Experimental Hypertension Exhibit of colored drawings of the fundus oculi in experimental hypertension and human hypertension, photomicrographs illustrating changes found in the ocular vascular system in experimental hypertension and human hypertension

DOHRMANN K PISCHEL, San Francisco

Statistics on Retinal Detachment Operations Exhibit showing statistical data in all cases of retinal detachments in which operation was performed at Stanford Hospital for past four years, results type of detachment, presence of holes and other facts

PHILLIPS THAGELSON, New York and POIRK RICHARDS, United States Indian Service Albuquerque, N M

Nature of the Filtrable Agent of Trachoma Exhibit presenting a summary of a series of experimental studies of trachoma which lead to the conclusion that trachoma is a virus disease

HERMANN M BURIAN, The Dartmouth Eye Institute Dartmouth Medical School, Hanover, N H

Peripheral Fusion and Eye Movements Exhibit showing that instrumentation in which projection lanterns and polarizing material differentiate the images formed in the two eyes is used to demonstrate that changes in the relative direction of the visual axes of the eyes can be produced by purely peripheral visual stimuli and that the fusional innervations resulting from peripheral stimuli can dominate foveal fusion

FREDERICK C CORDES, San Francisco

Collection of Old Ophthalmoscopes Exhibit of a collection of ophthalmoscopes including a replica of Helmholtz's ophthalmoscope together with old models dating from Jaeger down through the early electrical instruments instruments used by Fuchs Jackson Thorington de Schweinitz and others interesting and odd instruments, including a binocular reflecting ophthalmoscope

CARR I RICE, United States Public Health Service Washington D C and CONRAD PERLIN, New York

Medical Aspects of Aid for the Newly Blind Exhibit showing that forty states and territories are now cooperating with the Social Security Board in giving financial aid to the newly blind efforts made to build up high medical standards in the state programs having to do with this matter increasing interest shown in the various states in organized prevention of blindness and restoration of vision in needy persons in connection with aid to the blind state laws and state practice in the matters in varied and interesting avenues during the past two years

OTTO BARKAN, San Francisco

Glaucoma Investigations, Anatomic Classification and Recently Developed Surgical Procedures Exhibit of a series of plaster casts, drawings and photographs demonstrating the division of primary glaucoma into two main anatomic types according to the different mechanical causation of the increased intra-ocular pressure in each, critical survey of mode of action and sequelae of present day operations on the basis of this classification, effect of injection of physiologic solution of sodium chloride into the anterior chamber on the configuration of the iridic angle, demonstration of two surgical procedures devised to relieve the mechanical cause of two respective types of glaucoma photographs and case histories of goniotomy operation for deep chamber type of glaucoma and a recently devised surgical procedure for shallow chamber type of glaucoma

WALTER FINA, Minneapolis

Ocular Dynamics Exhibit demonstrating the various methods employed in studying ocular duction power, tabulated results of a series of cases in which these various methods have been employed, conclusions suggesting the comparative value of these methods

DANIEL B. KIRBY, New York

Cataract Extraction Motion picture demonstration in color showing preliminary iridectomy, capsulotomy extraction, discission of after cataract and intracapsular extraction with peripheral iridotomy

LOUIS LEHPFELD, Philadelphia

Vernal Conjunctivitis Motion picture demonstration in color describing the types of vernal conjunctivitis and offering clinical evidence of reproduction of clinical symptoms out of season by instillation of causative allergens in conjunctiva culdesac and showing that vernal conjunctivitis is an ocular manifestation of an allergy

WATSON GAILEY, Bloomington, Ill

Intracapsular Extraction of Senile Cataract Motion picture depicting the complete routine of cataract extraction, starting with the setup in surgery, method of draping the patient, close-up of the instrument table, operating table, lighting equipment, and so on, and method of lifting the patient from the operating table to the cart

CLIFFORD WALKER, Los Angeles

The Performance and Characteristics of Ocular Muscles with Respect to Separated Retina and Some Other Operations and Conditions Motion picture demonstration in color

Section on Laryngology, Otology and Rhinology

The representative to the Scientific Exhibit from the Section on Laryngology, Otology and Rhinology is Robert C. Martin, San Francisco

JOHN A. MARSHALL, University of California Medical Center, San Francisco

Clinical Dental Pathology Exhibit of photographs, photomicrographs, reproductions from roentgenograms and clinical specimens of extracted teeth showing the various lesions of the hard tissues in the initial, intermediate and terminal stages

WILLIAM J. MELLINGER, Santa Barbara

Petrous Apex of the Temporal Bone and Its Relations Exhibit consisting of dissected specimens of the petrous apex, sections of temporal bone in different planes, Dorello's canal dissected, skull specimens showing different types of the apex, and roentgenograms of petrous bone

WALTER P. COVELL, Hooper Foundation, San Francisco
L. J. BLACK, University of California, San Francisco, and
N. A. WATSON, University of California, Los Angeles

Recent Advances in Otologic Research Exhibit of charts and experimental portable hearing aid dealing with A (1) application of the selective amplification principle to hearing aids, (2) charts comparing bone conduction with air conduction for hearing of pure tones and speech sounds, B (1) charts and photomicrographs dealing with histopathologic changes in

the peripheral auditory mechanism for drug-injected animals and certain vitamin deficient animals, diagrams of equipment used for electrical hearing tests for eliciting responses charts illustrating results obtained, photograph records demonstrating differences between cochlear response and auditory nerve action potentials

A. C. FURSTENBERG, VAN M. PEET and I. JEROME HAUSER
University of Michigan Medical School, Ann Arbor, Mich

Present Status of Zinc Sulfate as a Possible Prophylaxis of Polymyositis Exhibit of charts summarizing original work on laboratory animals which led to the belief that zinc sulfate may possibly prevent polymyositis in human beings, description of difficulties encountered and inadequacies of originally described method of application of zinc sulfate, demonstration of a simplified technic for administration of zinc sulfate, slides and charts showing the present status of work, summary of questions to be answered and problems to be solved

SIMON L. RUSKIN, New York

Thrombus and Arterial Circulation of the Nose and Accessory Sinuses and Its Surgical Significance Exhibit of dissections and charts describing the circulatory mechanism, color photographs of the vessels as they are seen in the various surgical procedures, course of the blood supply from the carotids to the final distribution and the points for ligation and optimum lines for incision, photomicrographs of the vascular mechanism in the mucosa

Section on Pediatrics

The representative to the Scientific Exhibit from the Section on Pediatrics is F. Thomas Mitchell, Memphis, Tenn

ATHA THOMAS, T. L. HOWARD, WILLIAM T. STANER, F. I. DOBAS and ROY FORBES, Children's Hospital, Denver

Abnormal Calcification in Children Exhibit of roentgenograms and transparent photographs of postmortem specimens, illustrating abnormal calcium deposits in children, including faulty elimination, renal rickets, faulty nutrition, scurvy and rickets, glandular dysfunction, hyperparathyroid disease, inflammatory conditions, dermatomyositis and tuberculosis, traumatic conditions, myositis ossificans

KATSUJI KATO, Chicago

Blood Picture in Health and Disease Exhibit of drawings in natural colors of blood and bone marrow smears in various diseases, pictures of normal conditions at various age levels included for comparison

F. M. POTTINGER JR., Pottenger Sanatorium and Clinic, Monrovia, Calif

Study of Childhood Asthma as a Developmental Disease Exhibit of (1) photographs of asthmatic children showing deviations from the normal, (2) graphs showing some of the anthropometric measurements of asthmatic patients as compared with the standard tables, (3) photographs and charts of experimental animals which show symptoms like those found in allergic children and their deviation from the normal, (4) charts showing the importance of certain factors in the development of the disease

ERNST WOLFF, NORMAN EPSTEIN and T. HENSHAW KILLIP, Mount Zion Hospital, San Francisco

Prevention and Control of Impetigo of the Newborn Exhibit consisting of a pictorial demonstration of seven years' experience in the epidemiologic control of impetigo of the newborn charts depicting (1) the clinical picture, (2) bacteriologic observation, (3) mode of infection, with such human sources as the mother, nurse attending physicians, maids and porters, laundry workers, visitors and fellow nursing, together with other factors as delivery room technic, nursery technic, physical setup of nursery nursing organization and methods of medical examination, (4) organization for prevention and epidemiologic control, dealing with constant supervision of human and material sources of infection, nursery setup with photographs of floor plan of specially constructed equipment nursery routine and care and treatment of infected baby, (5) statistical review of clinical results over period of seven years

JOSEPH A. JOHNSTON, P. J. HOWARD, Henry Ford Hospital, and BRUCE DOUGLAS, Herman Kiefer Hospital, Detroit

Endogenous Tuberculous Reinfection, Adult-Type Lesions Appearing in Children After Their Removal from Contact Exhibit of x-ray films of children who showed on first examination either negative films or first infection types of disease but whose subsequent plates showed the development of the adult type

DAVID J. COHN, Michael Reese Hospital, Chicago

Oxygen Tent of New Design Exhibit of a comfortable and easily portable oxygen tent, using a small, simply constructed and efficient cooling unit, details of construction shown and operation demonstrated

Section on Pharmacology and Therapeutics

The representative to the Scientific Exhibit from the Section on Pharmacology and Therapeutics is Wallace M. Yater, Washington, D. C.

W. P. MURPHY, RAYMOND DILLON and ISABEL HOWARD, Boston

Blood Dyscrasias: Diagnosis and Effective Treatment Exhibit of charts stressing the importance of adequate, controlled treatment of some of the more important blood dyscrasias and depicting the several advantages of the maintenance treatment of the patient with pernicious anemia with highly concentrated solution of liver extract by intramuscular injection, motion picture in color showing important features of the clinical picture and of the blood in several diseases of the blood

A. C. ILL, R. R. GREENE and M. W. BURRILL, Chicago

Experimentally Produced Intersexuality in the Rat Exhibit of charts, photographs, whole mounts and wax plate models of intersexed rats, normal female and normal male rats, the intersexed rats are genetically female and have been masculinized by antenatal administration of male sex hormone

WALTERMAN WALTERS, E. J. KEPLER and R. M. WILDER Mayo Clinic, Rochester, Minn.

Adrenal Cortical Syndrome and Allied Disorders Exhibit dealing with studies in adrenal cortical tumors and allied disorders carried on over a period of years on patients who presented symptoms suggesting the adrenal cortical syndrome, differentiation of adrenal cortical tumors, pituitary basophilism, and so on, transparencies illustrating the appearance of patients prior to and subsequent to the removal of adrenal cortical tumors, motion picture describing the anatomy of the adrenal gland, its surgical lesions, results of operation and the surgical approach to the gland through a posterolumbar, retroperitoneal incision

JOSEPH G. HAMILTON, University of California Hospital, San Francisco

The Demonstration of the Measurement of the Rate of Absorption and Excretion of Certain of the Artificially Radioactive Elements Such as Sodium, Potassium and Chlorine Exhibit of charts, diagrams, Geiger counter and necessary accessories, experimental procedure permitting the observation by visitors of the method used, demonstration of the rate of excretion in the urine of these radioactive substances

R. N. HARGER, Indiana University School of Medicine, Indianapolis

Rapid Methods for the Detection of Poisons for Use in Emergency Cases Exhibit of reagents, apparatus and procedures used in the identification of certain common poisons in stomach contents, urine and blood, and the detection of a few volatile poisons in breath, description of original investigations in developing new procedures or simplifying older methods

ALFRED E. KOCHLER, Santa Barbara, Calif.

Comparison of the Intravenous Dextrose Tolerance with the Apparent Oral Tolerance Exhibit of apparatus for the intravenous injection of dextrose at a continuous constant rate over a period of two hours, blood sugar tolerance curves are shown and a comparison made with similar curves after the oral administration of dextrose demonstrating that the intravenous curve probably gives a better picture of the true tolerance,

as the oral curves may be markedly variable, owing apparently to variation in absorption

SAMUEL S. ALTSHULER, Detroit, and RUDOLPH LEISER, Eloise Hospital, Eloise, Mich.

Crystalline Insulin Exhibit dealing with (1) chemical properties, showing description of the crystals, preparation of crystalline insulin, analysis of the insulin, solubility and stability, (2) pharmacologic properties, showing effect on the blood sugar level as compared with unmodified insulin, role of zinc content and the effect of intravenous administration of crystalline insulin, (3) clinical use, showing results of the use of crystalline insulin in 150 diabetic patients over a period of two years and the method of administration

EDWIN E. OSGOOD, University of Oregon, Portland

Culture of Human Marrow as an Aid in the Evaluation of Therapeutic Agents Exhibit demonstrating a simple method of growing human bone marrow, permitting quantitative studies of the interaction of living human cells, noxious agents and therapeutic agents under accurately controlled conditions, results of studies of the toxicity of sulfanilamide, its action on infections with known numbers of various micro organisms with or without the presence of human cells or serum, illustrated under the microscope, with photomicrographs and wall charts, applicability of the method to studies of other agents

Section on Pathology and Physiology

The representative to the Scientific Exhibit from the Section on Pathology and Physiology is F. W. Konzelmann, Philadelphia

FRANK W. KONZELMANN, EDWARD WEISS, LAWRENCE W. SMITH, WALTER I. LILLIE and EDWIN S. GAULT, Philadelphia

Cardiovascular-Renal Disease, Clinical and Pathologic Correlation Exhibit of charts illustrating statistical data, classification of various types of cardiovascular-renal disease with the important points of diagnostic value presented in diagram form, changes in eyegrounds and gross and microscopic pathology of heart vessels and kidney illustrated by photographs and wax reproductions, wax reproductions of eyegrounds mounted in representative death masks illustrating in a practical way the picture seen through the ophthalmoscope

J. M. HILL, Department of Pathology, and LEWIS WATERS, Department of Medical Art, Baylor University College of Medicine, Dallas, Texas

Hemopoiesis Exhibit of transilluminated color photomicrographs demonstrating (1) the formation of red cells (erythropoiesis) giving phases of maturation, with classification of anemias due to decreased red cell production, (2) the white blood cells (Schilling differential), showing a graphic representation of formation of granular leukocytes, and the mechanism of their reaction in health and disease, (3) the aleukemic and leukemic states, explained on the morphologic and physiologic basis of the maturation of leukocytes, (4) models and charts illustrating use of laboratory tests in the diagnosis of familial hemolytic anemia

JACOB GFRSHON-COHEN, HARRY SHAY, SAMUEL S. FELS, THEODORE MERANZE and DAVID R. MERANZE, Philadelphia

The Thymus: Experimental Studies in Its Physiology Exhibit of charts, pictures, pathologic specimens properly mounted, roentgenograms and the experimental animals themselves arranged to demonstrate the effect of the thymus on the function of the genital system, the pituitary, adrenals and general body growth. The studies were made by inducing atrophy of the thymus gland by roentgen irradiation

H. J. CORPER, National Jewish Hospital, Research Department, Denver

Immunity in Tuberculosis, Historical and Experimental Exhibit demonstrating the various phases of experimental immunity and its production, illustrated historical album of immunity in tuberculosis

VIRGIL H. MOON and DAVID R. MORGAN, Department of Pathology, Jefferson Medical College, Philadelphia

Shock, Its Mechanism, Pathology and Sequelae Exhibit dealing with the mechanism of shock, shown by a diagram illus-

trating the operation of the "vicious circle", the pathology of shock shown by gross specimens and by illuminated photomicrographs from human cases and from animals, presentation of progressive stages of pulmonary edema and pneumonia as sequelae of sublethal shock, explanation of the differentiation of shock from hemorrhage

HENRY C SWEENEY and ROSALIND KLASS, Municipal Tuberculosis Sanitarium, Chicago

X-Ray Diffraction Analysis as Applied in Pneumococcosis Exhibit of illustrations photographs, charts, transparencies and gross pathologic specimens showing possibilities of x-ray diffraction as an analytic procedure in the determination of detrimental silica diffraction patterns of various minerals as well as a typical silica pattern compared to patterns obtained by analysis of powdered human lung tissue from patients who were exposed to various dusts, patterns of normal and tuberculous lungs, chemical analysis for silica microscopic and gross pathology

FRANK B YOUNG Long Beach Calif

Diagnosis of Acute Alcoholism by Chemical Methods Exhibit showing apparatus for securing alcohol from the exhaled air saliva and urine by use of distillation under partial vacuum, colorimeter for comparison of test solution with solutions of standardized strength technic of making tests, based on the reduction of potassium bichromate by alcohol

HERMANN BECKS University of California, George Williams Hooper Foundation for Medical Research and College of Dentistry, San Francisco

Experimental Production of Osteodystrophia Fibrosa Cystica in Dogs by Deficient Diets Exhibit of photomicrographs of histologic material showing experimental production of osteodystrophia fibrosa cystica in dogs by deficient diets

CHARLES WEISS HAROLD BRUNN and A KAPLAN Mount Zion Hospital San Francisco

Cellular Immunity A Comparison of humoral and tissue immunity to staphylococcus toxin B Cellular proteinases in inflammation and in experimental tuberculosis in rabbits Exhibit (a) dealing with immunity to staphylococcus toxin (b) dealing with cellular proteinases in inflammation and in experimental tuberculosis in rabbits with data on the cathepsin dipeptidases and carboxypolypeptidases of polymorphonuclear white blood cells and monocytes of inflammatory exudates as well as those produced by the intrapleural injection of the phosphate of the tubercle bacillus

CHEVALIER L JACKSON Philadelphia

Cancer of the Larynx Exhibit showing histopathology especially as determined by biopsy and its importance in selection of method of treatment early diagnosis and its relation to end results demonstrated by transparencies gross specimens and motion pictures, technic of laryngofissure laryngectomy and irradiation, with statistics of five year cures

F W HARTMAN and VICTOR SCHELLING Henry Ford Hospital, Detroit

Studies on Hexyl-Chloro-M Cresol and Other Carbocyclic Antiseptics Exhibit of charts, tables, cultures and photographs presenting experimental and clinical observations on a new chemical of high antiseptic activity, observations on other chemicals of the same general composition, effect of acids on the antiseptic activity of this group of compounds, comparative value of this group of carbocyclic antiseptics contrasted with that of the salts of heavy metals as indicated by phenol coefficient studies, toxic index studies, and clinical applications

BENJAMIN T TERRY, Tacoma General Hospital, Tacoma Wash

Three Aids in the Rapid Diagnosis of Tissues Exhibit showing (1) practical gross diagnosis, (2) a new, easily made inexpensive microtome for fresh and fixed tissues (3) an inexpensive easily made instantaneously acting differential stain for fresh or fixed tissue Clinical facts presenting a

problem will be given In order to arrive at a solution surgical or autopsy tissues will be shown and important practical gross diagnostic features will be stressed The diagnosis will be established by a microscopic examination of sections cut on the new microtome and stained by the new stain Lesions, technic, and interesting and important diagnostic points will be shown in moving pictures Those interested can learn to make and use the microtome and stain Abundant opportunity to practice under supervision will be afforded

HARRY C SCHMEISSER and JOSEPH L SCIVANI University of Tennessee, Memphis

History of Medical Art Exhibit of photographs showing ancient, medieval, modern and contemporary medical art

HENRY DOUBILET, RALPH COLP and I L GERBER The Mount Sinai Hospital New York

Sphincter of Oddi—Experimental and Clinical Studies Exhibit of original apparatus shown for the kymographic recording of the resistance of the human sphincter of Oddi to continuous perfusion demonstration of actual practical bedside procedure effect of drugs shown by kymographic tracings, demonstration of physiologic principles of visualization of the biliary tract with iodized oil, methods for the detection of pancreatic reflux and for visualization of the pancreatic duct in the human being, instrument for the endocholedochal section of the sphincter of Oddi results of both experimental and clinical endocholedochal sphincterotomy, as regards the safety and effectiveness of the procedure

WILLIAM STEVENSON and B S KLINE Mount Sinai Hospital Cleveland

Exact Photographic Medical Illustration Exhibit of prints with colors of original photographed specimens including gross clinical and gross and microscopic pathologic specimens exactly reproduced, color prints of color transparencies, steps in the preparation of the exact color prints and color transparencies of gross and microscopic specimens and of color prints

LEWIS WATERS Department of Medical Art, Baylor University College of Medicine, Dallas, Texas

Art and Photography as Applied to Medical Illustration Exhibit of drawings photographs and transilluminated pictures in black and white and in color illustrating methods of medical illustration including methods of making motion pictures, presentation of a new color process for photomicrography and clinical photography

JOHN D CORBIT JR, Philadelphia General Hospital, and HERMAN A SHELANSKI, University of Pennsylvania, Philadelphia

Silver Picrate in the Control of Bacterial, Yeast and Protozoan Infections Exhibit showing methods of diagnosis for infections due to *Monilia albicans* and *Neisseria gonorrhoeae* and for infestations due to trichomonad flagellates, stramen, and cultural methods for these organisms together with the effect on them of silver picrate in vitro and in vivo

Section on Nervous and Mental Diseases

The representative to the Scientific Exhibit from the Section on Nervous and Mental Diseases is Roland P Mackay Chicago Motion pictures will be shown in addition to the exhibits in an adjoining area

C W IRISH Los Angeles

Spontaneous Cerebral Vascular Lesions and Distributions of the Major Vessels Exhibit of photographs of pathologic specimens demonstrating the various sites and types of cerebral vascular lesions color negatives of injected cerebrum different colors demonstrating the distribution of each major vessel external views of the cerebrum, sagittal sections and coronal sections

A E BENNETT AVIS PURDY and HELF JORDA Bishop Clarkson Memorial Hospital Omaha

History and Development of Modern Psychiatric Nursing Exhibit of pictures and charts showing the historical evolution of modern psychiatric treatment from 4000 B C to the present

sition from primitive, inhumane nursing management to the modern periods of reform in state hospital development and the mental hygiene movement, the present trend of treating the mentally ill through well equipped psychiatric units in general hospitals, illustrated through photographs, charts, teaching manual and motion pictures

CHARLES P LARSON, Western State Hospital, Fort Steila-
coom, Wash

Mountings of Neuropathologic Specimens Exhibit of speci-
mens of neuropathologic interest, including unusual tumors,
aneurysms, and other specimens mountings are of the watch
glass type, the total cost per specimen averaging less than
60 cents, method of mounting will be demonstrated the finished
product is notable for its maximum visibility and beauty

TRACY J PUTNAM and H HOUSTON MERRITT, Boston City
Hospital, Boston

*Experimental and Clinical Studies of New Anticonvulsant
Drugs* Exhibit presenting a list of old and new compounds
tested, diagrams of method of testing on animals and charts
of results, formulas of drugs found effective in animals,
statistics of patients treated with most effective compounds,
representative case histories

G WILSE ROBINSON and G WHISL ROBINSON JR Kansas
City, Mo

*Experiences and Studies in the Use of Insulin in Various
Forms of Psychoses* Exhibit of (a) graphs, each of which
represents the entire course of treatment of individual patients
of a series of selected cases showing behavior, with a quanti-
tative graph of behavior changes from week to week weekly
laboratory determinations taken every hour during the course
of the treatment, with changes in blood sugar blood counts
hemoglobin and differentials, and metabolism as measured by
the consumption of oxygen, clinical charts carried continuously
from beginning to end of the entire course of treatment,
and observable clinical reactions as measured by depth of coma
severity of spasmodic reactions and psychic state during each
individual treatment, (b) presentation of results in the treat-
ment of acute alcoholic psychoses with insulin (c) presenta-
tion of technical equipment and improvements modifications
of original procedure, which have aided in promoting under-
standing and minimizing complications

HENRY R VIETS and ROBERT S SCHWAB Massachusetts
General Hospital, Boston

*Myasthenia Gravis Diagnosis and Treatment with Pro-
stigmine* Exhibit of charts giving the principal symptoms age
of onset and prevalence the use of prostigmine as a diag-
nostic measure elucidated by charts and motion pictures as
experienced at the Massachusetts General Hospital

PAUL A OLFARI, Mayo Clinic Rochester Minn HAROLD
N COLE, Cleveland J LARLF MOORE Baltimore, JOHN H
STOKES Philadelphia, Uno J WHIT Ann Arbor Mich
THOMAS PARRAN, R A VONDERLIEHR and LIDA J USHION,
Washington, D C

Results of the Treatment of Tabes Dorsalis Exhibit con-
sisting of a group of graphs showing the value of different
systems of treatment symptoms most readily influenced value
of early treatment of syphilis versus late treatment of neuro-
syphilis and the value of the fever therapy in tabes dorsalis

ABRAHAM LOW, Chicago

Mazal Shock Therapy A motion picture demonstrating
one of the newer treatments of functional psychoses

J R JAEGER, Denver

Neurosurgery Operations Motion picture demonstration in
color showing the various standard operations performed on
the brain, spinal cord and peripheral nerves

Section on Dermatology and Syphilology

The representative to the Scientific Exhibit from the Section
on Dermatology and Syphilology is Clark W Finnerud Chi-
cago A special feature of the section is a group of exhibits
on industrial dermatoses

JOSEPH V KLAUDER, Philadelphia

Swine Erysipelas Infection Exhibit of charts concerning
the infection in (1) swine, (2) the organism, (3) the infection
in man, (4) occupation of patients involved, photographs of
the infection in swine and in man, specimens of the infection
in swine, stained smears of the organism, cultures of the
organism, colored motion pictures of the infection in man

THEODORE CORNBLEET and HEARA SCHORR, Chicago

Is Psoriasis a Metabolic Disease? Exhibit showing the sugar
content of the skin in health and its variations, the changes
in the normal content in psoriasis (both in the lesions and the
normal skin), various agents and maneuvers used in the treat-
ment of psoriasis and how they affect the sugar content of
the skin, data used to support a metabolic theory of the cause
of psoriasis

J E MOORE, Baltimore and R A VONDERLIEHR, United
States Public Health Service, Washington, D C

The Diagnosis of Syphilis Exhibit of lantern slides pre-
senting the differential diagnosis of syphilis by clinical and
laboratory means in complete and condensed form

GEORGE V KULCHAR and JOHN F CARD, Stanford Univer-
sity Hospital, San Francisco

*Divided Doses of Typhoid Antigen H (Formalinized) in
the Treatment of Neurosyphilis* Exhibit of (1) charts illus-
trating the method of preparation of the antigen by formalde-
hyde precipitation, (2) description of the method of its use in
the treatment of neurosyphilis, particularly in patients not suit-
able for other forms of fever therapy, (3) charts illustrating
daily fever curves in response to graduated doses, (4) charts
illustrating clinical and serologic results

HARRY E ALDERSON, San Francisco

Rhinoscleroma Exhibit of photographs and photomicro-
graphs of all rhinoscleroma cases reported in California with
many examples from San Salvador

HIRSH C MILLER and HOWARD MORROW, University of Cali-
fornia Medical School, San Francisco

Coccidioidal Granuloma Exhibit demonstrating (1) the
clinical types of the disease by photographs and x ray films,
(2) the pathology with specimens and photomicrographs, (3)
the cultural characteristics and types of the organism, (4)
immunity as shown by skin reactions, (5) habitat of the
organism, (6) results of animal inoculations and (7) inter-
esting historical facts

SAMUEL AYERS JR and NELSON PAUL ANDERSON, College
of Medical Evangelists, Los Angeles

Natural Color Photography in the Teaching of Dermatology
Exhibit of lantern slides illustrating various disorders of the
skin showing recent development of improved color film to
photograph cutaneous lesions in their natural color Demon-
stration of apparatus and technique employed

ARTHUR E INCELS, San Francisco

Poison Oak Plants, Extracts Dermatoses and Treatment
Exhibit showing poison oak dermatitis, poison oak remedies
and so on pressed poison oak plants in all its stages, products
of poison oak extract, mode of administration, different phases
of poison oak dermatitis, photographs of conditions

MAURICE DORNE, A W STILLMANS and T K LAWLESS,
Chicago

Treatment of Argiria Motion picture demonstration in
color of argiria the technique of treatment and the results

MARY A MARCUS, New York

*Micrologic, Histologic and Therapeutic Observations in
Psoriasis* Exhibit of photomicrographs of psoriatic cases,
photomicrographs showing the micro organism in the lesions
of psoriasis, photomicrographs of the micro-organism pre-
pared from culture at different stages which demonstrate
different phases of the development of the micro organism for
its specific identification

Symposium on Industrial Dermatoses

United States Public Health Service Cooperating with the
Section on Dermatology and Syphilology

LOUIS SCHWARTZ, United States Public Health Service, New York, and MARION B. SULZBERGER, Postgraduate Medical School, Columbia University, New York

Occupational Dermatoses Exhibit of charts, photographs and moulages, miscellaneous small samples of actual materials, such as rubber and wood, which have caused industrial dermatoses

HARRY R. FOERSTER, Milwaukee

Occupational Dermatoses Exhibit of photographs of occupational dermatoses

JOHN G. DOWLING, Boston

Occupational Dermatitis Exhibit of transparencies showing the location and type of eruptions found in various industrial workers, a series of pictures depicting the various stages seen in the production of dermatitis factitia

C. GUY LANE, Boston

Education in Occupational Dermatoses Exhibit of posters, indicating the needs and purposes of such education, the group to whom it should be directed, plans for course in occupational dermatoses, and outline of subjects to be covered

Section on Preventive and Industrial Medicine and Public Health

The representative to the Scientific Exhibit from the Section on Preventive and Industrial Medicine and Public Health is Paul A. Davis, Akron, Ohio

ERNEST C. DICKSON, CHARLES E. SMITH and ARTHUR LAEK JR., Stanford University School of Medicine, San Francisco

Acute Primary Type of Infection with Fungus Coccidioides Exhibit of diapositives and roentgenograms representing the acute primary stage of coccidioides infection and the secondary stage of coccidioides granuloma, diapositives showing the development of chlamydospores, which are the etiologic agent of the primary type, and of the endospores, which cause spread of the infection in coccidioides granuloma, spot map of the incidence of valley fever, the local name for the primary form in the San Joaquin Valley and a chart indicating the clinical course of the primary form

EDWARD MATZGER, Southern Pacific Railroad Hospital, San Francisco, and LEROY ABRAMS, Stanford University, Palo Alto, Calif.

Allergies in Railroad Workers—Methods Used in Control Exhibit of mounted specimens collected in California, Oregon, Idaho, Arizona, Utah, New Mexico, Texas and parts of northern Mexico, charts indicating the chronology of pollination at various centers of population, charts indicating abundance of plants and relative amounts of pollen produced, microscopic demonstration of pollens, charts classifying nine years of clinical allergic studies in 1234 patients, factors of the seasonal and perennial groups, methods of treatment, importance of botanic data to seasonal complaints, and therapeutic results

HERMANN SOMMER and K. F. MEYER, Hooper Foundation, University of California Medical Center, San Francisco

Plankton and Paralytic Shellfish Poisoning Exhibit showing (1) distribution of the disease, (2) epidemiology along the Pacific Coast from Alaska to Los Angeles, correlated with laboratory observations, (3) cultures of the poisonous plankton, (4) marine aquarium with three kinds of shellfish involved, (5) symptoms in animals and man with treatment and prevention

S. E. GOULD, Eloise Hospital, Eloise, Mich., and Wayne University College of Medicine, Detroit and I. FOREST HUDDESON, Michigan State College, East Lansing, Mich.

Undulant Fever (Brucellosis) Exhibit of models and transilluminated photographs and diagrams, illustrating (1) the sources and methods of spread of human infection (2) fever charts and anatomic location of disease in acute and chronic cases, (3) diagnostic methods, including intradermal brucellergen test, rapid agglutination test, opsonic test and culture, and (4) methods of control of infection and effect of treatment with brucellin

JOSEPH FELSEN, New York

Prevention, Diagnosis and Treatment of Acute Bacillary Dysentery Exhibit showing (1) epidemiologic studies, the prevention and control of institutional and hospital outbreaks, educational program for the public in the prevention and control of diarrheal disease, recognition of the new forms of bacillary dysentery by the family physician, mass vaccination, (2) typical and atypical cases of acute bacillary dysentery, the diagnostic laboratory triad, the characteristic three stage pathology, (3) principles of therapy, different methods of therapy for each of the three stages of acute bacillary dysentery, use of vaccine to prevent the chronic phase of the disease

Section on Urology

The representative to the Scientific Exhibit from the Section on Urology is R. S. Ferguson, New York

WIRT B. DAKIN, Los Angeles

Foreign Bodies in the Urinary Bladder Exhibit of a large number of foreign bodies found in the urinary bladder, together with descriptions of each case and a review of the literature

HENRY SANGREE, Philadelphia, and ROBERT HOTCHKISS, Cornell Medical Center, New York

Fertility in the Male: Clinical and Surgical Treatment Exhibit of charts, models and photographs of congenital anomalies and endocrine disturbances, colored drawings, photomicrographs and microscopic slides portraying normal and abnormal sperm, together with a complete analysis of cases treated, motion picture in color illustrating the operation of epididymovasostomy, the various anatomic and inflammatory conditions causing infertility in the male and photomicrographs showing the action of normal and abnormal sperm in various mediums

HENRY A. R. KREUTZMANN, M. L. POLSKY and BENJAMIN STRAUSS, San Francisco

Anatomy of the Intramural Portion of the Normal Ureter Exhibit showing the intramural portion of the ureter, adjacent bladder wall and trigon sectioned and various strains of these sections showing the muscles, nerves and connective tissue in this region. The true relationship of the various structures is depicted by means of a transparency case and also by dissections

ROGER W. BARNES, Los Angeles

Embryology of the Prostate Exhibit consisting of models of the prostate of the human fetus ranging in age development from twelve weeks to term, photomicrographs of cross sections and longitudinal sections of the prostate, and a fetus representing the age at which each model is made

ROBERT A. MACARTHUR, Detroit

Hematuria Exhibit of transparencies illustrating practically all the pathologic conditions causing hematuria throughout the genito-urinary tract, these conditions are demonstrated by means of roentgenograms, cystograms, pyelograms, drawings, cystoscopic views in color and colored photographs

Section on Orthopedic Surgery

The representative to the Scientific Exhibit from the Section on Orthopedic Surgery is Norman T. Kirk, San Francisco

PHILIP LEWIN, Chicago

Newer Conceptions and Methods of Teaching Orthopedic Surgery to Undergraduate Students Exhibit of translated roentgenograms and anatomic models dealing with the embryology development, anatomy, physiology and chemistry of orthopedic structures, and illustrating congenital defects, deformities and disabilities of developmental nutritional, postural, paralytic, infectious, myogenic, neurogenic, traumatic, fibrogenic, vascular and neoplastic origins

FRANK A. LOWE, San Francisco

Congenital and Acquired Clubfoot: Manipulation and Surgical Models Exhibit of models of clubfoot before and after correction, motion pictures of cases before and after treatment

various methods of moleskin adhesive traction for fracture treatment, sand bag weight and pulley for fractured femurs

LEROY C ABBOTT, F C BOST and JOHN B SAUNDERS, San Francisco

Leg Lengthening and Fractures of the Hip Exhibit illustrating the anatomy and operative technic of the lengthening of the tibia and fibula by means of charts, drawings, photographs, anatomic dissections, x-ray transparencies and apparatus, dissections showing the main features of the anatomy of the leg and of the actual operation apparatus illustrating its historical development, fractures of the neck of the femur demonstrated by dissections and x-ray transparencies

K K SHERWOOD, Seattle

Management of Chronic Arthritis Exhibit of photographs roentgenograms and charts, emphasizing (1) the importance of the complete diagnosis in all cases of chronic arthritis, (2) the value of laboratory tests, especially vitamin C determinations and sedimentation and cell volume studies, (3) that roentgenograms should be used in ruling out disease other than arthritis and in giving a prognosis but not as a means of making the diagnosis, (4) the importance of general therapeutic measures (rest, diet, symptomatic medication, physical therapy, orthopedic measures and psychotherapy), the importance of dividing atrophic and hypertrophic arthritis into small groups presenting the same clinical syndromes

L D SMITH, Milwaukee

Mechanism, Treatment, Internal Fixation of Cervical Fracture of the Femur Exhibit of model of pelvis and hip joint showing the action of muscles on the joint and on the neck of the femur, method of reduction demonstrated, human specimens showing the anatomy of the hip in relation to its fracture and its treatment, films and slides of internally fixed hip fractures, instruments for inserting the four flanged spike, thus maintaining reduction in a fractured hip

CHARLES MURRAY GRATZ, New York

Fascial Adhesions in Low Back Pain and Arthritis Exhibit dealing with fascial adhesions shown anatomically, radiologically and histologically, rationale of selecting cases in which fascial adhesions should be treated, result of treating fascial adhesions over a period of years, a new method of measuring limitation of motion of the back

J E M THOMSON and C FRED FERCIOT, Lincoln, Neb

Surgical Treatment of Comminuted Fractures of the Patella Exhibit of models drawings and roentgenographic films demonstrating the advantages of surgical treatment of certain fractures

DAVID H KLING, Los Angeles

Physiology and Pathology of Synovial Membrane and Synovial Fluid Exhibit of photographs tables and descriptions of precipitation phenomena of synovial mucin, comparative sedimentation, bilirubin content of joint effusions fat in traumatic effusions, enlargements of photomicrographs showing the cytology of joint effusions in different types of arthritis, photomicrographs showing systematic method of dissection of the knee joint, which demonstrates variations of structure and function

C HOWARD HATCHER and PETER M WASBOTEN, University of Chicago Clinics, Chicago

Correlation of Pathologic and Roentgenologic Characteristics of Skeletal Diseases Exhibit of histologic preparations demonstrating the pathologic characteristics of various bone and joint diseases with x-ray transparencies correlating the pathologic and roentgenologic observations accompanied by colored photomicrographs, panels are prepared illustrating bone tumors, tuberculous arthritis, chronic nontuberculous arthritis, osteomyelitis and aseptic necrosing lesions of bone

RALPH SOTO-HALL and KEENE O HALDEMAN, San Francisco

Neurotrophic Joint Disease (Charcot Joint)—Its Development Diagnosis and Treatment Exhibit of roentgenograms which were studied to throw light on the causative factors

A statistical tabulation of the entire series of patients with neurotrophic joint disease indicating the relative value of clinical signs and laboratory aids in diagnosis, photographs, drawings and roentgenograms illustrating a new method for the operative fusion of Charcot joints in two stages

S L HAAS, San Francisco

Growth Changes in the Spine, An Experimental and Clinical Study Exhibit showing that definite length growth changes in the vertebrae of animals takes place at the epiphysal plate, injuries to the epiphysal cartilage plates, comparative study of the growth changes in the vertebrae of man and of animals both by roentgenograms and by histologic study after fusion operations

RUDOLPH SKARDA, University of California Medical Center, San Francisco

Anatomicosurgical Preparations Exhibit of a series of preparations of actual dissections prepared by a new technic, of value in teaching, in refreshing the surgeon on anatomic details and showing surgical approaches

HENRY W MEYERDING, Mayo Clinic, Rochester, Minn

Spondylolisthesis, An Etiologic Factor in Baclache Exhibit consisting of (1) roentgenograms illustrating site and extent of deformity and postoperative surgical fusion, (2) anatomic models in wax demonstrating defects and surgical treatment, (3) motion pictures illustrating various deformities encountered on inspection of the spine, extent of limitation of motion and phases of conservative and surgical treatment

J B DE C M SAUNDERS, University of California Medical School, San Francisco

Development and Growth of the Fetal Skeleton Exhibit of fetal skeletons prepared by a new technic, charts, photographs and diagrams demonstrating inherent factors which control and determine characteristic form and structure, results of quantitative examination of growth changes in the bones, relationship of sidereal time to development, effect of predetermined growth rates as modifying skeletal form and proportion

HENRY H KESSLER, Newark, N J

Rehabilitation of Industrial Amputation Cases Exhibit of photographs of arm amputation cases including plaster models, prosthesis and motion picture demonstration

Section on Gastro-Enterology and Proctology

The representative to the Scientific Exhibit from the Section on Gastro Enterology and Proctology is J A BARGEN, Rochester, Minn

H F HANEY, Department of Physiology, University of Oregon Medical School, Portland

Experimental Approach to Some Problems in Gastro-Enterology Exhibit showing I Relation of extrinsic nerves to the function of the cardia (a) diagram to show location of nerve sections, (b) diagram of balloon setup used in obtaining tracings, (c) tracings obtained II The use of chronic accessible closed intestinal loops in the study of absorption, (a) diagram of loop and method of entering loop, (b) preserved loop specimens, (c) sagittal section through closed loop and anterior abdominal wall with needle in place III A technic for end to end anastomosis of the small intestine, (a) diagram of operative procedure, (b) preserved specimens, (c) histologic picture at various stages in process of healing Photomicrographs and sections

STANLEY H MENTZER, University of California Medical School, San Francisco

Gallstones Exhibit of gallstones of every known variety, without duplication, gathered from more than 40,000 specimens

ALLAN J HRUBY, LEO HARDT, JOHN S COULTER, CLEMENT MARTIN CARROLL COOK and KARL HENRICHSEN, Municipal Tuberculosis Sanitarium, Chicago

Gastrointestinal Tuberculosis Exhibit of roentgenograms and transparencies of gastrointestinal and pulmonary conditions, pathologic specimens and proctoscopic color photographs,

charts summarizing the diagnosis and treatment of gastrointestinal tuberculosis, charts showing a study of diagnostic data that have been confirmed by postmortem examination charts showing the results of a comparative study of the treatment of gastrointestinal tuberculosis

WENDELL G. SCOTT, St. Louis

Kymographic Studies of Gastrointestinal Movements Exhibit of a series of diagrams and roentgen kymograms demonstrating the principle and method of roentgen kymography, films showing alterations in the peristaltic movements of the stomach in various diseases, motion picture demonstrating the peristaltic movements of the small intestine and colon

DAVID J. SANDWEISS, H. C. SALTZSTEIN and A. A. FARBYAN, Detroit

The Relation of Sex Hormones to Peptic Ulcer Exhibit will consist of charts showing clinical data bearing on this subject. It will include mounted specimens of the stomach and jejunum of Mann-Williamson dogs showing the effect of various sex hormones on these experimental ulcers. The effect of these hormones on cinchophen ulcers will also be presented.

MALCOLM R. HILL, Los Angeles

History of Illustration in Proctology Exhibit consisting of reproductions and art drawings depicting the progress medical science has made in dealing with disease as related to proctology, the relative progress made in the art of illustration.

CLAUDE C. TUCKER and C. ALEXANDER HELLWIG, St. Francis Hospital, Wichita, Kan.

Proctologic Tumors: Diagnostic Difficulties and Pathology Exhibit of transparencies and pathologic specimens illustrating the different tumors in the anorectal region and showing that clinical differentiation between harmless lesions and malignant tumors is often impossible and routine histologic examination of all removed tissue is indicated.

FELIX CUNHA and FRED C. BLAKE, San Francisco

Intra-gastric Photography and Its Clinical Application, Use of the Flexible Gastroscope in the Diagnosis of Gastric Lesions Exhibit demonstrating camera used, actual method of taking snapshot and method of supplying current cameras outlining principles maintained in construction and the principles of physics or optics involved in taking a photograph, source of generation of power for the lighting up of the stomach used in taking the photograph gastroscope with charts showing the principle of physics involved construction, and artists drawings outlining various pathologic conditions encountered and easily differentiated a motion picture demonstrating the entire technique of flexible gastroscopy.

Section on Radiology

The representative to the Scientific Exhibit from the Section on Radiology is E. E. DOWNS, Woodbury, N. J.

HARRY H. BOWING and R. E. FRICKE, Mayo Clinic, Rochester, Minn.

Carcinoma of the Uterine Cervix: A Summary of Treatment and Results Exhibit of charts and graphs showing (1) that the average age is 49, (2) epithelioma is the chief lesion (93.5 per cent), (3) a large majority of patients (84 per cent) had lesions of high grade malignancy (Broders), (4) a large number of the patients had inoperable lesions (93 per cent), (5) Results of treatment (five year cures): stage 1, 69.2 per cent, stage 2, 60.2 per cent, stage 3, 29.7 per cent, stage 4, 6.5 per cent, (6) Palliation occurs in all cases, (7) Hospital mortality of 1 per cent occurred entirely in the inoperable group, (8) The three year cure rate shows improvement after more complete treatments were given, (9) Technique of the radium and roentgen therapy as outlined for an average case with a stage three involvement with universal tube applicator, size, amount of radium and filtration, the treatment time, intervals between applications and length of course in days near or at the end of the radium treatment, roentgen therapy given as outlined, (10) reexaminations are done at three month intervals for the first year, at six month intervals the second year and every year thereafter.

JAMES F. KELLY and D. ARNOLD DOWELL, Omaha

Roentgen Treatment of Acute Peritonitis and Other Infections with Mobile Apparatus Exhibit illustrating the advantages of a specially designed mobile therapy apparatus to be used at the bedside in the treatment of serious acute infections such as peritonitis, gas gangrene, pneumonoma, surgical mumps, Ludwig's angina, erysipelas and other infections, clinical data of many cases treated with this apparatus as well as the technique and advantages and indications for its usage.

H. O. MAHONEY, Oak Park, Ill., B. J. ANSON and ROY F. DENT, Northwestern University Medical School, Chicago

Study of Sectional Anatomy by Means of the Roentgen Ray Exhibit demonstrating the preparation of sections and the technique employed in roentgenographing them, representative selection of roentgenograms of sections showing advantages which roentgenography provides in the study of sectional anatomy.

RICHARD DRESSER, Boston

Million Volt Roentgen Therapy Exhibit of photographs of the electrostatic belt-conveyor generator developed at the Massachusetts Institute of Technology, data in the form of charts and graphs regarding the physical properties of million volt roentgen rays, data regarding immediate clinical results.

HENRI COUTARD and MAX CUTLER, Chicago Tumor Institute, Chicago

Carcinoma of the Larynx—Diagnosis and Radiation Treatment Exhibit containing illustrations classifying the various forms of laryngeal carcinoma, demonstrating methods of diagnosis and indicating their radiologic treatment.

WILLIAM E. HOWES, Brooklyn

Planigraphy Exhibit of drawings to demonstrate the principles of planigraphy, series of transparencies showing roentgen ray films and planigraphic films in the same case including foreign body in the mediastinum precollapse and postcollapse tuberculous cavities mediastinal tumors, metastatic lung tumors, roentgen ray pleural pulmonitis and other conditions.

EDUCATIONAL CLASSIFICATION

Government and National Organizations

The educational exhibits include those exhibits from national and state organizations and government institutions which are put on in the name of the institution rather than of individuals and which are intended to show progress in the particular activities with which those institutions deal.

These exhibits are not open to medal awards, but a special certificate of merit is presented to the best exhibit in this classification.

UNITED STATES NAVY, San Diego, Calif.

Medical Department, U. S. Navy Exhibit showing medical equipment and practice in hospitals, aviation, submarines and marine corps.

CHILDREN'S BUREAU, U. S. DEPARTMENT OF LABOR, Washington, D. C.

Safe Home Delivery Exhibit of bed and other equipment for aseptic technique used in home delivery, charts showing number and percentage of live births occurring in the hospitals and homes in urban and rural areas, charts showing number and percentage of urban and rural births delivered without a physician, poster material for adequate hospital equipment for serious complications of childbirth, essentials for safe home delivery.

AMERICAN HEART ASSOCIATION, New York

Exhibit of educational material including books, pamphlets and leaflets on various phases of cardiovascular disease.

AMERICAN HUMAN SERUM ASSOCIATION, Los Angeles

Convalescent Human Serum Exhibit of charts showing series of cases treated and protected with the various convalescent serums, display of the various types of convalescent serums both liquid and dried, demonstration of new apparatus used in the handling of human convalescent serum.

AMERICAN PHYSIOTHERAPY ASSOCIATION, Berkeley, Calif
Your Physical Therapy Technician—Schools Training Therapists Exhibit showing physical therapy schools on an animated map posters showing the theory and practical courses required in the approved schools, cartoons entitled "All in the Day's Work"

NATIONAL TUBERCULOSIS ASSOCIATION, New York
Diagnosis of Tuberculosis Exhibit of charts and roentgenograms illustrating the difficulty of making diagnoses of pulmonary tuberculosis unless the roentgen ray is used

UNITED STATES PHARMACEUTICAL ASSOCIATION, San Francisco
Exhibit illustrating methods for determining the hydrogen ion concentration of some official products the preparation of buffer solutions and their application demonstrations of official products used in ophthalmic and dermatologic practice, and a special exhibit of the official ointments

AMERICAN SOCIETY FOR THE CONTROL OF CANCER, New York
Exhibit of charts and diagrams showing the objectives and progress of the Women's Field Army since its inception summary of educational and organization activities

AMERICAN PHARMACEUTICAL ASSOCIATION, Washington, D C

National Formulary Preparations Exhibit of National Formulary preparations of interest to prescribing physicians, examples of preparations of therapeutic importance representing convenient and satisfactory dosage forms, and of vehicles designed to aid the physician in prescribing attractive and palatable prescriptions

ADVISORY BOARD FOR MEDICAL SPECIALTIES, Pittsburgh
Exhibit of charts graphs and literature describing the work of the Advisory Board for Medical Specialties and of the examining boards for certification in medical specialties including the American Boards of Ophthalmology, of Otolaryngology, of Obstetrics and Gynecology, of Dermatology and Syphilology, of Pediatrics, of Psychiatry and Neurology, of Radiology, of Orthopaedic Surgery of Urology, of Pathology, of Internal Medicine and of Surgery

NATIONAL SOCIETY FOR THE PREVENTION OF BLINDNESS, New York

Prevention of Blindness—A Public Health Program Exhibit of charts illustrative material and motion pictures pertaining to the various aspects of sight conservation from the public health point of view namely antepartum care care of the eyes at birth vision testing, venereal diseases and eye health eye conditions in midlife and later, and material on the causes of blindness

NATIONAL BOARD OF MEDICAL EXAMINERS, Philadelphia
Exhibit of charts describing the work and progress of the National Board of Medical Examiners including graphic presentation of the results of its examinations

AMERICAN SOCIAL HYGIENE ASSOCIATION, New York
Syphilis in Pregnancy and the Prevention of Congenital Syphilis Exhibit of photographs transparencies specimens, charts and graphs showing the pathology of syphilis in pregnancy its diagnosis and treatment, and the prevention of congenital syphilis

AMERICAN COLLEGE OF CHEST PHYSICIANS, Monrovia, Calif
Results of Collapse Therapy in Pulmonary Tuberculosis Exhibit of roentgenograms showing pictures of the chest before and after instituting collapse therapy, plates illustrating artificial pneumothorax, phrenicotomy, pneumolysis and thoracoplasty pictures describing each of the plates and the various operations

AMERICAN SOCIETY OF CLINICAL PATHOLOGISTS, Registry of Medical Technologists, Denver

Exhibit of charts teaching the importance of employment by hospitals and physicians of properly trained medical technologists charts giving data regarding approved training schools descriptive literature, blank forms

EXHIBITS OF ORGANIZED MEDICINE

The exhibits from the California Medical Association, Indiana State Medical Association and the headquarters group of the American Medical Association cover various activities of organized medicine

CALIFORNIA MEDICAL ASSOCIATION

Organizational Activity Exhibit of charts, photographs and graphs demonstrating some fifteen diversified organizational activities of the California Medical Association together with the work of special committees and councils and also representation of the distribution of membership in the several councilor districts of this great state

CALIFORNIA MEDICAL ASSOCIATION, CANCER COMMISSION

Cancer Its Diagnosis and Treatment Exhibit of photographs roentgenograms and pathologic specimens illustrating the problem involved in the diagnosis, treatment and prevention of cancer from the standpoint largely of the general practitioner, stressing importance of early diagnosis and possibility of cure in the common forms if diagnosis is early and proper treatment instituted

INDIANA STATE MEDICAL ASSOCIATION, BUREAU OF PUBLICITY AND THE EXECUTIVE COMMITTEE, Indianapolis

An Antidote for State Medicine—the Preventive Medical Health Program of the Indiana State Medical Association Exhibit of charts, maps, models and plans describing and depicting the Indiana program, copies of the *Journal of the Indiana State Medical Association* showing how physicians of the state are kept informed with regard to the program, and copies of releases from the Bureau of Publicity showing how the public is kept informed, literature prepared by the Bureau of Publicity

AMERICAN MEDICAL ASSOCIATION

Council on Foods Exhibit outlining various phases of the Council's activities, charts of food values in terms of dietary essentials, publications of the Council on the nutritional significance of foods and on normal and therapeutic diets

AMERICAN MEDICAL ASSOCIATION

Council on Physical Therapy Exhibit consisting of apparatus models and charts demonstrating certain fundamental physical principles of physical agents models showing layout of physical therapy departments for hospitals with fifty, 200 or 300 beds and over, charts portraying the recent accomplishments of the Council on Physical Therapy

At stated intervals, the following motion picture films will be shown

Aids in Muscle Training
Occupational Therapy
Underwater Exercises
Effects of Heat and Cold on Circulation of Blood
Effects of Massage on Circulation of Blood
Therapeutic Exercise for the Shoulder Joint Following Dislocation
Contraction of Arteries and Arteriovenous Anastomoses
Treatment of Compression Fracture of the First Lumbar Vertebrae

AMERICAN MEDICAL ASSOCIATION

Council on Medical Education and Hospitals Exhibit of statistics, diagrams and maps dealing with medical education, medical licensure and hospitals, publications of the Council, including essentials and revised lists of hospitals approved for residencies in specialties, hospitals approved for intern training schools for laboratory technicians, schools for physical therapists, and schools for occupational therapists

AMERICAN MEDICAL ASSOCIATION

Bureau of Legal Medicine and Legislation Exhibit showing effectiveness of basic science laws in preventing the licensing of incompetent practitioners, posters relating to legal medicine and legislation

The TECHNICAL EXPOSITION

A Panorama of Medical Progress

● The importance of the Technical Exposition to the medical profession is well demonstrated by the importance which the exhibitors themselves attach to it. Whether the locale is on the Eastern Seaboard, in the Middle West, or on the Pacific, one will invariably find most of the representative medical firms present with carefully planned exhibits and a capable staff of attendants. This year the Exposition in San Francisco will be true to type. It will include some 200 firms, occupying a total of almost 50,000 square feet in the great hall of the San Francisco Auditorium.

● In this vast array of products and services needed in the every-day practice of medicine, the physician will find a definite educational stimulus. It will, in truth, be a vivid panorama of "What's New and Useful to the Physician?" On every hand will be evidence of forward strides in research, important technical advances, improvements in standard products and services.

● The whole spirit of this great gathering will be one of service and courtesy. At every booth the physician will find well qualified representatives eager to discuss questions of mutual interest. He will discover that the principal aim of the exhibitor is to tell an interesting, informative story. Every display will have some special features worthy of careful study, whether it be pharmaceuticals and biologicals, medical books, instruments, apparatus, electrical equipment, dietetic products, or specialized services. Visitors are urged to take full advantage of the educational opportunities offered by the exhibits and visit them repeatedly.

● The Technical Exposition is located in close proximity to the Registration, the Postoffice and the Scientific Exhibits and will be a convenient place to meet friends or spend the time before, after, or between meetings. It will be open from 8 30 A. M. to 6 00 P. M. each day, closing Friday at noon.

Will C. Brown
Superintendent of Exhibits

APPARATUS and INSTRUMENTS

INCLUSIVE ALOE DISPLAY

The new Radcliff retractor, the DeBakey blood transfusion unit and other instruments and equipment will be shown by A. S. Aloe Company in Booths 97, 98 and 99. A feature will be the display of Aloe Steeline modern treatment room furniture in a full color range, also physical therapy equipment including the new Aloe X-ray and the Aloe short wave unit. In Booth 110 the company will show a complete line of clinical laboratory equipment. See page 96.

INFUS O THERM DEMONSTRATIONS

At Booth 18 the American Medical Specialties Company will exhibit the Infus O Therm, an instrument that permits blood temperature at needle point during intravenous infusion. Demonstrations will be given to show how a control dial gives any heat degree at a drop per minute rate, assuring the solution entering the vein at blood temperature under constant heat control. The new Amisco Oscillometer will also be demonstrated. See page 60.

AMERICAN STERILIZER DISPLAY

The American Sterilizer Company will exhibit in Booth 116 an improved design of the 1065 head end controlled surgical operating table to be displayed in conjunction with an American Luminaire Surgical Light. There will also be shown a small pressure steam sterilizer arranged for temperature control with the newly developed American Vacuum Drier. Intended to facilitate the drying of dressings and to eliminate the escape of steam into the sterilizing room. In addition a new office type electric instrument sterilizer will be demonstrated.

NEW CASTLE ITEMS WORTH SEEING

At the Wilmot Castle exhibit, Booth 77, there will be on display several pieces of apparatus, brand new in idea and purpose. Surgeons particularly will want to be sure to visit the Castle booth. See page 70.

(Continued on next page)

NEW HEMATOLOGICAL CASE

Bird Parker products to be exhibited at Booth 120 include Rib Back blades stainless steel renewable edge scissors, Laher Lock forceps and the new B P hematological case. This case for obtaining bedside blood samples for red white and differential counts has several novel features including correction factor pipettes stains for diluting fluids. See page 102

TO SHOW HOW SYRINGES ARE MADE

Becton Dickinson & Company will occupy spaces 35-39. Here a complete line of products will be shown grouped according to fields of practice. In addition to this complete display of syringes needles Aseptio syringes thermometers Ace bandages diagnostic instruments and general utility items a demonstration of glass syringe making and thermometer blowing will be presented daily. Trained technical men will be in attendance at all times to answer questions concerning instruments displayed. See page 79

ORTHOPAEDIC AND X RAY TABLE

The Bell Fracture orthopaedic and x-ray table will be exhibited in Booth 20. Several new features will be stressed including the new Hitchcock two blade sacral rest. A live model will be used to show the various positions and adjustments of the table. The Bell Wire Gun and several other interesting bone instruments will also be shown. See page 92

OF INTEREST TO BONE SURGEONS

The DePuy Manufacturing Company will present new Vitallium items for bone work in Booth 22—dressed screws, Sherman plates Venable type plates Smith Peterson nails and White type nails. Pick-up screws fixation screws and ordinary nails for treatment of fractures in the seniles will be on display. Also the new combination Padula stretcher and hyperextension table for handling injured backs and the Carl P. Jones Well Leg splint for treatment of hip fractures. See page 100

SEE THE DEVILBISS DISPLAY

The complete DeVilbiss line of atomizers steam vaporizers and nebulizers will be shown in Booth 182. Specially featured will be illustrations based on x-ray research graphically depicting the coverage afforded by the atomizer in the application of solutions to the nose and throat. Copies of the illustrations for reference may be secured from the representative in charge.

AIDS TO BETTER HEARING

Acousticon extends a cordial invitation to all physicians to visit Booths 239 and 240 where the firm will display its latest scientific developments—the Acousticon Aurogaug which permits the selection of the Acousticon assembly best suited to the patient's hearing requirements, the Coronation Acousticon and the Acousticon Crystal Acousticon which employs the cathode ray principle used in television permitting the patient to see what he hears.

MECHANICAL RESUSCITATION

A study which appeared in the April Surgery Gynecology and Obstetrics on Mechanical Resuscitation in Advanced Forms of Asphyxia will be featured in connection with exhibit of the E & J Resuscitator Booth 262. The paper gives an account of animal experiments in as-

phyxia at Cornell Medical Centre and also of clinical results obtained in the treatment of advanced asphyxia with the E & J Resuscitator. See page 108

PNEUMATOLOGY APPARATUS

Means for the administration of helium in oxygen therapy as well as anesthesia is one of the new items of pneumatology which will be displayed in Booth 4 by the Loregger Company Inc. See page 74

NEW SUCTION AND PRESSURE UNIT

The Gomco Surgical Manufacturing Corporation Booth 143 will display their new hospital suction and pressure unit with stainless steel cabinet. Physicians are invited to note particularly the remote control attachment which permits the entire pump unit to be placed a distance away from operating table allowing the entire ether output to be controlled by the small remote control unit. See page 74

HEIDBRINK GAS MACHINE

The Heidbrink kinetometer gas machines equipped with two chambered carbon dioxide absorbers for maximum economy in the use of some of the new anesthetic gases will be on display in Booth 180. Also to be shown are new improved oxygen therapy units such as the combination motor motorless oxygen tents and the nasal tube inhaling device.

NEW TYPE BED PAN

In Booth 231 the Jones Metal Products Company will exhibit their modern Relax Bed Pan which because it is scientifically designed permits easy roll-on placement and provides more comfort for the patient as well as greater convenience for the nurse.

"BABY ALL" EQUIPMENT

In Booth 241 there will be demonstrated a miniature low-priced formula room for the baby at home also a new development known as the All-Nite Vaporizer-Humidifier which provides medicated or plain vapors continuously for 12 hours or less. See pages 76 and 82

MacGREGOR INSTRUMENT DISPLAY

A visit to Booth 173 of the MacGregor Instrument Company will give you an opportunity to examine the complete line of Vim products. In addition to Vim needles of Firth-Brenley stainless steel and Vim emerald springs there will be a full display of the new Vim Steri-Tectors Vim Needle-Trainers and Vim Carry-Alls. Surgeons are especially invited to see the Vim exhibit of Iron Arm surgeons needles.

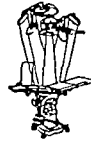

INSTRUMENTS FOR THE SPECIALTIES

The V. Mueller & Company exhibit Booths 72-73 will cover highlights in the various fields of surgery. A large section will be devoted to the latest developments in ophthalmic instruments as well as those for ear nose throat and plastic work. Instruments and equipment representing the strides made in orthopaedic urological and general surgery will be displayed also modern ether vapor and vacuum apparatus and other equipment. See page 100

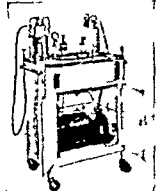

MODERN SURGICAL LIGHTS

At Scanlan-Morris Company's exhibit Booth 236 demonstrations will be given of modern surgical illumination with Operax Multibeam and Operax Surg-O-Ray lights which are now equipped with new type twin-filament projection lamps to give a selection of intensity and provide a safeguard against lights out hazards. The Scanlan-Balfour general operating table and its adaptability to the newer surgical techniques will also be featured.

SUCTION AND PRESSURE APPARATUS

The Sklar Manufacturing Company exhibit Booth 92 will feature the new improved heavy duty hospital model of the Bellevue Suction and Pressure Unit. It will also include the complete line of Sklar suction and pressure units as well as the Tompkins Portable Moorhead Rolls. Ideal and other pumps for clinic and office use. See page 96

HEARING AID DEMONSTRATIONS

Recent developments in electrical hearing aids technique of individual fitting and audiometers will be demonstrated at the Sonotone Corporation Booth 215. An unusual demonstration of how speech and music sounds to persons with different types of hearing impairment will be conducted by means of special phonograph recordings played through bone and air conduction receivers. Also demonstrated will be the Sonotone Audiometer a note worthy high precision instrument.

DIAGNOSTIC EQUIPMENT

BAUMANOMETER TO BE FEATURED

The exhibit of the W. A. Baum Company Booth 165 will show the latest Kompak Model Lifetime Baumanometer with many exclusive features, including the completely recessed entrance tube. The ever popular desk and wall models will also be prominently displayed. A new one-piece rubber bulb made of highest quality latex another important improvement to the Baumanometer will be awaiting your critical examination. See page 27

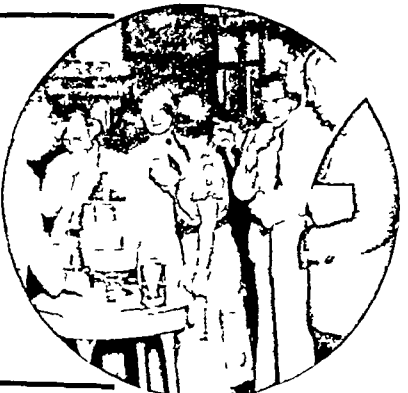

ELECTRICAL INSTRUMENTS

The new Lempert-LeVee Headlite will be demonstrated in Booths 177 and 229 by Cameron Surgical Specialty Company. Latest developments in electrically lighted diagnostic and operating instruments for all parts of the body will also be shown. Of special interest will be the new inexpensive office model of the radio knife and other electrosurgical units for cutting coagulation desiccation and fulguration ranging in size up to the hospital model for the most radical and heavy surgery. See page 15

CAMBRIDGE CARDIAC APPARATUS

The Cambridge Instrument Company will exhibit two new instruments in Booth 119—the Simpli-Trol Portable Model Electrocardiograph which weighs only 30 pounds complete, and the Portable Electrocardiograph-Stethograph which permits the tracing of the electrocardiogram and stethogram consecutively on the same instrument. Other Cambridge cardiac diagnostic instruments will also be shown. See page 86.

CONSTANT SPEED CENTRIFUGE

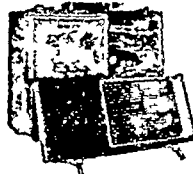

The new G310 constant speed centrifuge with uniform timing will be shown at Booth 200. In addition to demonstrations of the quiet dependable performance of this standard comparative instrument, the Electric Manufacturing Company will have on display the G310 graduated molded Lucite tubes which are unbreakable, with no variation in weight or content.

A STOMACH CAMERA

For the first time on the Pacific coast the Gastro Photo camera for photographing the interior of the stomach will be shown by Gastro Photo Laboratories in Booth 128. A large number of stomach photographs normal and pathological obtained with this tiny camera will be on display, and competent men will be in attendance to give complete information regarding this ingenious instrument. See page 98.

ELECTRICAL STETHOSCOPE

The Crosby Electric Company, national distributors of Western Electric scientific equipment, will feature instruments of interest to the medical profession such as the electrical stethoscope in Booth 130. The background of the booth will emphasize the nationwide service that Crosby renders. It will show a large map of the United States with each of the 83 cities where Crosby offices are located indicated by an electric bulb.

**JONES METABOLISM EQUIPMENT**

The Jones Metabolism Equipment Company in Booth 118 will feature as they display the Jones Motor Basal, the Super Basal, and the Automatic nitrogen determination metabolism equipment. A special feature of the metabolism equipment is that it contains no water and requires no circulation in the determination of the BMR. Another special feature of the dis-

play is the new method for determining the normal from the nitrogen metabolism. The Super Basal is an apparatus adjustable to the size of the patient. See page 87.

MUSCLE TESTING

New methods in nerve and muscle testing will be featured in the exhibit of Lundquist diagnostic and therapeutic apparatus. Of particular interest to the neurologist and the physical therapist will be the demonstration of Chronoviv, the newest method of electrodiagnosis. The new direct-reading automatic Chronovimeter and the Chronoviv low voltage generator will be featured. The manufacturer will be present to explain the operation of the new instruments. Booth 217.

METABOLISM AND CARDIOGRAPHY

Three outstanding new developments in modern diagnostic apparatus will be shown at Sunborn Company's booth No. 82. The new Sunborn waterless metabolism tester companion to the famous water-sealed Model P-1-S will be exhibited. Both models will be on view. The latest Cardette achievement—automatic elimination of AC interference in heart records made by this portable electrocardiograph will be demonstrated. Developments in a new combination cardiograph-stethograph providing an electrocardiogram stethogram (heart sound record) and amplified heart sound for auscultation are also planned to be shown. See page 29.

SEE THIS ANIMATED DISPLAY

The animated display of the Taylor Instrument Companies in Booth 49 will show how Tyco's blood pressure instruments operate. Also don't miss the mechanical hammer which proves the durability of the glass tube in the Tyco's mercurial manometer. The new flat glass Taylor Binoc fever thermometer will be displayed along with the Pavaux unit the famous glass boot for treating circulatory diseases of the extremities.

CERTIFIED
Tyco's
INSTRUMENTS
—10-Year Guarantee

BODY CAVITY INSTRUMENTS

At Booth 183 you can inspect the new Welch Allyn bronchoscopes, interesting developments in rectal instruments shown for the first time, and laryngoscopes representing important advances in construction. A complete line of dependable instruments for diagnosis in all body cavities will be presented.

CLAPP'S CHOPPED FOODS

Huold H. Clapp, Inc. will show their newly developed line of Chopped Foods for young children at Booth 129. The display will consist of 8 varieties of vegetables, soups and fruits which cover in

texture and providing more roughage than strained foods are a valuable contribution to the control of nutrition in early childhood. See page 61.

WHY EAT BREAD?

In Booth 18, the department of nutrition of the American Institute of Baking will have a display showing why good bread is an economical and reliable source of abundant and easily digestible food energy. Scientific literature accepted by the Council on Foods of the American Medical Association describing the proper place of white bread in normal and reducing diets will also be available. See page 33.

**NEW NUCOA EXHIBIT**

Doctors attending the convention who would like to learn more about New Nucleo cordially invited to visit the Best Foods booth (No. 191) and taste this wholesome spread for bread. An interesting series of photographs stressing the wholesome conditions under which New Nucleo is manufactured will show how New Nucleo is made. The exhibit will feature the recent addition of Vitamin A to the product. See page 110.

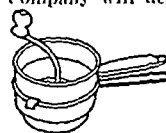

New
NUCOA

BORDEN'S 81st YEAR

A warm welcome awaits all physicians at the Borden Booth No. 51. Representatives will gladly provide information on Borden products, notably Dryco, Special Dryco, Klim, Beta Lactose, Metcalf Soule Prescription Products, and Borden's Irradiated Evaporated Milk. See page 21.

**EASY WAY TO STRAIN FOODS**

In Booth 208 the Loley Manufacturing Company will demonstrate how easily and quickly fresh cooked vegetables and fruits are mashed or strained with the Loley Food Mill made of steel, rust proof, acid proof and easy to clean. It will be shown in three sizes.

**HAVE A CUP OF SANKA COFFEE**

At Booth 17 you will be served with a cup of delicious Sanka Coffee which is a choice blend of Central and South American coffees from which 97% of the caffeine has been removed. The new drip grind is as well as regular grind of Sanka will be on display together with other General Foods products of interest to physicians. See page 35.

**STRAINED FOODS FOR INFANTS**

Cerber Products Company cordially invites you to visit Booth 89 and inspect their strained foods on display. Literature for professional use only and also some for distribution to mothers or adult patients.

DIETETIC PRODUCTS**AMERICAN CAN EXHIBIT**

All registrants at the Convention are cordially invited to call at Booths 52 and 53 where information will be available concerning those aspects of commercially canned foods which are of greatest interest to the medical profession. Literature on canned foods designed specifically for the physician's use will also be on display.

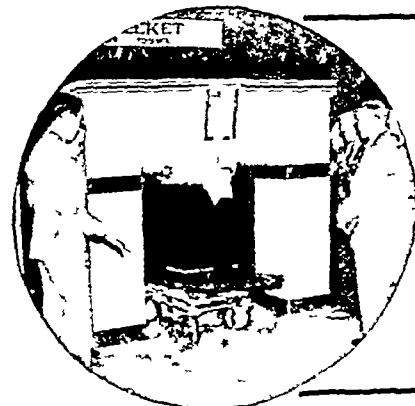

CARNATION EXHIBIT

Some little-known factors in evaporated milk quality will be emphasized in the Carnation Company's exhibit Booths 15 and 16. The display will show how the Carnation

experimental farms are developing high producing stock to improve the herds supplying its evaporating plants and the work of Carnation field men in supervising raw-milk sources to insure a constant supply of clean fresh milk. The scientific processing of Irradiated Carnation Milk will also be illustrated. See page 72.

tients on therapeutic diets will be exhibited, and on request will be sent you later See page 97

GOLDEN GATE MACARONI
All of the fine semolina and egg noodle products of the Golden Gate Macaroni Company will be displayed at Booth 210. Especially featured will be Lancy Pastino, a new special fine grain type of macaroni product recommended by the firm for use in the diet of invalids and children.

COOL PINEAPPLE JUICE
Dole pineapple products from Hawaii will be represented at Booth 193. Here convention guests will be served a cool, soothing drink of pure unsweetened Dole Pineapple Juice. A colorful reminder of glamorous Hawaii itself will be featured, the display including a pictorial presentation of Hawaiian scenes plus a slide film showing the growth of pineapple and the picking of canned Hawaiian Pineapple and Pineapple Juice. See page 114.

HEINZ STRAINED FOODS
In order that you may see the natural fresh color and uniform consistency of Heinz Strained Foods, their display will present in an attractive manner all 12 varieties. A representative will be present to answer questions and a copy of the fifth edition of their Nutritional Chart will be sent to physicians who register at the exhibit in Booth 141. See page 113.

LITERATURE FOR PHYSICIANS
Reports of clinical research on the use of Irradiated Evaporated Milk in infant feeding, treatment of milk allergy and dietary management of peptic ulcer will be available at Booth 152, also free manuals of instruction giving formulas for milk mixtures and recipes for low cost family feeding. The new Sweeney and Buck monograph on "How to Feed Young Children in the Home" will be shown and you can easily arrange for complimentary copy.

MOTION PICTURES TO BE SHOWN
Mead Johnson & Company will feature some new sound on film motion pictures on pediatric subjects, also some new artistic interests at Booths 168, 169, 271, 272 and adjoining rooms. This will be the first exhibit on the Pacific coast of the Mead Johnson collection of ancient nursing bottles, pap boats and feeding spoons which has increased greatly in scope and value since it was shown at the Philadelphia session in 1931. Among the new products will be Oluc for the feeding of premature. See back cover.

MELLIN'S FOOD EXHIBIT
Physicians attending the Session are invited to visit the Mellin's Food Company's exhibit which will occupy Booth 87. Well informed representatives will be on hand to discuss the adjustment of feeding mixtures to meet the nutritive requirements of infants during their first year, and other problems.

NEW INFANT FEEDING SCHEDULES
At Booth 14 the National Dairy Council will present an exceptionally fine set of infant diet schedules using fresh milk for infants for use exclusively by the physician.

in prescribing the baby's diet from infancy to ten months. National Dairy Council representatives will be on hand to answer questions and take registrations for copies of the booklet.

A COMPLETELY MODIFIED MILK
Similac, a completely modified milk for infants deprived of breast feeding, will be displayed by M & R Dietetic Laboratories, Inc. Booth 71. Qualified representatives will gladly explain the value of the zero curd tension of Similac as it applies to both normal and special feeding cases. See page 116.

OIL PAINTING TO BE SHOWN
Nestle's Milk Products, Inc. in Booth 78 will exhibit an original oil painting as the main feature of their display. The painting represents a nursery scene and is the work of Stephen Csoka who executed the canvas especially for Nestle. See pages 94-95.

EVAPORATED MILK PLANT
An actual working model of a milk condensing plant in miniature, every part constructed to scale, will be exhibited in Booths 131 and 135. The exhibit will offer an opportunity to obtain information about the production of Irradiated Pet Milk and its uses in infant feeding and general dietary practice. Miniature Pet Milk cans will be given to each physician who visits the booth. See page 124.

TRY A BANANA MILK SHAKE
You are cordially invited to visit the United Fruit Company's Booth (No. 142) and sample a refreshing banana milk shake made before your very eyes from the fresh ripe fruit mixed with cold milk and a scoop of vanilla ice cream. Here also you will find the latest information developed by research on the food value and the varied uses of the banana.

ORANGE GRAPEFRUIT BEVERAGE
Blended Orange and Grapefruit Juice, a new and delicious addition to the Dr. Phillips line of canned citrus fruits and juices, will be featured at Booth 57 with other products of the firm.

STOKELY'S BABY FOODS
The fourteen different items in the Stokely line of baby foods which are prepared by a special fine chopping process known as comminuting, will be displayed at Booth 27. Stokely's Tomato Juice and Stokely's Grapefruit Juice will also be included in the exhibit.

VEGEX FOR VITAMIN B
At Booth 149 Vegex will be featured as a potent source of the B Vitamin Complex. Its extrinsic factor potency and results in anemia, new data in child and mother feeding and recent results in heart and diabetic and pellagra disorder studies will be shown, including the control tests used in biological assay. The palatability and simple food uses of Vegex in child and adult diets will also be demonstrated. See page 109.

MEDICAL BOOKS

MANY NEW MEDICAL WORKS
D. Appleton-Century Company will exhibit their entire line of medical works in Booth 44. Their "Practitioners Library of Medicine and Surgery" will be exhibited complete in its 13 volumes, also the complete set of the new Postgraduate Surgery. The thirteenth revised edition of Osler's Principles and Practice of Medicine will be shown for the first time. The new Essentials of Pathology by Lawrence W. Smith and Edwin J. Gault and other recent works will be included.

SHOWN FOR THE FIRST TIME
Downey's Handbook of Hematology in 4 volumes of 3,200 pages will be shown for the first time at the booth of Paul B. Hoerber, Inc. No. 107. The firm will also show the first copies of "The Culture of Organs" by Alexis Carrel and Charles A. Lindbergh, Lasher's Industrial Surgery, Sheehan's Reproductive Plastic Surgery, Corner's "Attaining Manhood," Parler's "Methods of Tissue Culture" and other new and forthcoming publications. See pages 16 and 17.

medicine and surgery. Of particular interest are three new monographs which are nearing completion for the meeting but may not be released until late in June—"Symptomatology and Differential Diagnosis in Diseases of Children," by Sanford Blum, A.B., M.S., M.D., a handbook of "Roentgen and Radium Therapy," by A.J. Delario, B.S., M.D., and "Diseases of the Ear, Nose and Throat," by Francis L. Lederer, B.S., M.D. See pages 11 and 12.

LEA & FEBIGER BOOKS
At Booth 86 Lea & Febiger will exhibit the following new works: Brenner's Pediatric Surgery, Pohle's Theoretical Principles of Roentgen Therapy and Clinical Roentgen Therapy, Steel's Biological and Clinical Chemistry, Craig & Faust's Parasitology, Long & Goldberg's Social Hygiene, Weinzierl's Hygiene, Fishberg on Heart Failure, Davidoff & Dyke's Normal Encephalogram, Rowes' Clinical Allergy, Saxl's Pediatric Dietetics and Thorndike's Athletic Injuries. Many new editions will also be shown. See pages 6 and 7.

NEW LIPPINCOTT PUBLICATIONS
Dr. Max Thorek's Modern Surgical Technique in 2 volumes containing over 2,000 illustrations will be shown for the first time at the Lippincott Booth (No. 100). Other new important publications to be on display are Experience in the Management of Fractures and Dislocations by Dr. Phillip Wilson and associates present-

MAGMILLAN MEDICAL WORKS

The Macmillan Company extends a cordial invitation to visit its exhibit of new and outstanding books at Booth 23. Among recent publications to be displayed are the following: Foraker's 'Leukemia and Allied Disorders', Jones' 'Digestive Tract Pathology', Kurtz's 'Orthodiascopy', Holman's 'Arteriovenous Aneurysm', Nelson-Cratin's 'Syphilis Gonorrhea and the Public Health', Streeker-Chambers' 'Alcohol', One Man's Meat, Mann's 'Developmental Abnormalities of the Eye', and Guedel's 'Inhalation Anesthesia'. See pages 18 and 19.

EXHIBIT OF MOSBY COMPANY

Among the many new books to be exhibited by the C. V. Mosby Company at Booth 93 are: Jensen's 'The Heart in Pregnancy', the 5th edition of Porter and Carter's 'Management of the Sick Infant and Child', Pottenger's 'Symptoms of Visceral Disease', Pruitt's 'Hemorrhoids', Watson's 'Hernia Rea's Neuro-Ophthalmology', the 5th edition of Crossen's 'Operative Gynecology', and the 6th edition of Clendenen's 'Methods of Treatment'. Approximately 100 other volumes will complete the exhibit. See pages 8, 9, 10 and 11.

LOOSE LEAF MEDICAL BOOKS

Thomas Nelson & Sons invite you to visit their exhibit in Booth 43. The Nelson Loose-Leaf Medicine, Loose-Leaf Surgery, Loose-Leaf Diagnostic Roentgenology (many volumes in one) and the new semi-annual replacement pages showing the latest advances in medicine and surgery, will be on display.

FROM THE OXFORD PRESS

In Booth 51 Oxford University Press will have on display an extensive line of medical books including 'Management of the Pneumonias' by Dr. J. G. M. Bullock, 'Radiation Therapy' by Dr. I. I. Kaplan, and the standard work 'Applied Physiology' by Dr. Samson Wright. 6th edition together with 'Oxford Loose Leaf Medicine'. See page 20.

'LOOSE LEAF MEDICAL BOOKS

In Booth 171 W. I. Prior Company will show their full line of loose-leaf medical works, including Tice's 'Practice of Medicine', Lewis' 'Practice of Surgery', Wock, Pemberton and Coulter's 'Principles and Practice of Physical Therapy', Davis' 'Gynecology and Obstetrics', and 'Practice of Pediatrics' by Brennemann. A vast sum of money has been spent during the past year to keep all of the Prior works up-to-date with medical advances and representatives will be glad to tell all visitors about the advantages of the loose leaf service. See pages 22 and 23.

OUTSTANDING SAUNDERS BOOKS

W. B. Saunders Company will exhibit at Booths 84 and 85 a complete line of books for the medical, dental, nursing and allied professions. Included will be a brand new edition of Beckman's 'Treatment', Buie's 'Practical Proctology', Herman's new 'Urology', new edition of Cecil's 'Medicine', Gifford's 'Ophthalmology', Padgett's 'Surgical Diseases of the Mouth and Jaws', Merritt and Iremont-Smith on the 'Cerebrospinal Fluid', the new (1938) 'Mayo Clinic Volume', Wiprud's 'Business Side of Medical Practice', Bastedo's 'Viteria Medica' and many others. See pages 3, 4 and 5.

SIX UNIVERSITY PRESSES EXHIBIT

New books in medicine and surgery from six University Presses will be shown in a joint exhibit. The Presses cooperating in the display are Yale University Press, University of Pennsylvania Press, University of Illinois Press, University of Minnesota Press, Columbia University Press, and the University of Chicago Press. A representative of the University of Chicago Press will be in charge of the exhibit. Booth 126.

ADVANCE COPIES OF NEW BOOKS

At Booth 1 William Wood & Company will show advance copies of important books including Portmann's 'Operative Otolaryngology', Cabot and Adams' 'Physical Diagnosis', Appleton and Tenapertoff's 'Surgery and Radiological Anatomy', Feldman's 'Clinical Roentgenology of the Digestive Tract', Friedenwald's 'Secondary Gastrointestinal Disorders', Henderson's 'Adventures in Respiration', Bierman's 'Medical Applications of Short Wave Willsie's 'Chronic Intestinal Toxemia' and many standard works. See pages 20 and 21.

A. M. A. PUBLICATIONS

A. M. A. periodicals, pamphlets and reprints as well as the American Medical Directory, Index Medicus and other books will be found in Booth 107A. Also in Booth 268 there will be a miniature stage production which, by means of animated figures shows the value of Hygiene to the physician and his patients.

MISCELLANEOUS

A "DIFFERENT KIND OF EXHIBIT"

A distinctive type of exhibit will be that of the American Seating Company. Booths 176 and 178. As an aid to the medical profession in influencing the present widespread movement toward modernizing school equipment, because of its importance as a factor in public health, the firm will present models and graphs showing just how seats affect the visual and general welfare of children. Doctors will be interested in the thoroughgoing research which underlies this presentation. See page 62.

AZNOE'S EMPLOYMENT SERVICE

An experienced representative of Aznoe's National Physicians Exchange will be on hand in Booth 70 to offer the services of this organization to medical men and hospital executives who are considering additions or changes in office or hospital personnel. Available applicants include phy-

sicians, nurses, dietitians, technicians or other medical assistants. This service is free to employers. Persons seeking an appointment or contemplating a change in employment are also invited to call.

MOTION PICTURE EQUIPMENT

Bell & Howell will exhibit and demonstrate various types of 16 mm movie cameras, projectors and accessories.

New models in cameras will include the 701 semi-professional with 400 magazine motor drive and single frame exposure device. A new projector will be the 138-J two-case 11mm sound with booster amplifier giving 14 watts output. Also a new free booklet on medical movie making will be available. Booth 16.

WOVEN NAME TAPES

Visitors at Booth 116, of J & J Cash Inc., manufacturers of woven name tapes and insignia for hospital identification marking will have the opportunity of seeing the model of a loom which makes the articles. Also featured will be a special style of woven name tape known as D-51 used by superintendents of nurses, dietitians and nurses on the pocket of their aprons or uniforms. See page 119.

AT THE EASTMAN KODAK BOOTHS

The Eastman Kodak Company will feature a collection of interesting clinical radiographs in Booths 137, 138 and 139. Shown also will be both medical and pictorial motion pictures in full color made with Kodachrome. Also there will be a large display of clinical subjects in both black and white and natural color in the form of transparencies and prints, the latter also in color employing the Wash Off Relief process. Technical representatives will be in attendance to answer any questions. See insert between pages 62 and 63.

WILL SHOW RUBBERIZED MATERIALS

Water and dust proof lightweight rubberized sheetings and garments for office, hospital and home use will be demonstrated at Booth 244 by the Holland Rantoso Company Inc. Rantosilk, a rubber calendered silk, Hollandex, a rubber calendered lawn, and Rantogrip, a non-slip sheeting will be included in the exhibit. All physicians are invited to call.

BABY TRAINING BOOKS

A newly revised edition of 'Training the Baby' will be offered free to physicians in limited quantities. In Booth 60 where Little Folks and other toilet training accessories will be shown. New interesting photographs will also be available. An illustrative mural of Comfy-Safe AutoSeat, the only item outside of habit training aids made by Juvenile Wood Products Inc. will be featured in the exhibit.

IF YOU HAVE A HOBBY

The monthly magazine 'Associations de' voted to collectors of books and autographs, prints and etchings, antiques and glass stamps and coins and photography and travel as they relate to these hobbies has been selected as the official organ of the American Physicians Art Association and will be on display at their booth No. 261. The June issue which will be featured will reproduce the works of over

MODERN RECORD SYSTEMS

The McCaskey Register Company in Booth 40 will gladly explain to physicians their 'One Writing' record system and show how it offers a convenience and savings on account of the ready visibility and accessibility of individual records. Here is an opportunity to pick up valuable information on efficient management of medical practice. See page 92.

MEDICAL BUREAU FACILITIES

In Booth 88 an experienced representative will offer the facilities of the Medical Bureau an organization which acts as counselor in problems of medical personnel to physicians hospital administrators clinic managers and executives in the medical field. The records of physicians who have specialized in the various branches of medicine as well as the records of hospital executives graduate nurses technicians social workers and dietitians will be available to those interested in the completion or reorganization of their staffs. See page 67.

PROFESSIONAL PROTECTION

The Medical Protective Company invites you to visit Booth 184. The representative who will be in charge is thoroughly trained in professional liability underwriting and is entirely familiar with the principles of the reciprocal rights and duties of a doctor and patient and with the circumstances peculiar to that relationship. He will be glad to explain how his Company meets the exacting requirements of adequate liability protection which are peculiar to the professional liability field.

CALL AT PHILIP MORRIS BOOTH

Philip Morris & Co. Ltd. Inc. in a new exhibit Booth 117 will demonstrate the method by which it was found that Philip Morris cigarettes in which diethylene glycol is used as the hygroscopic agent are less irritating than other cigarettes. Their representative will be happy to discuss researches and problems on the physiological effects of smoking. See page 117.

NORTHWESTERN MUTUAL LIFE

The medical department of the Northwestern Mutual Life Insurance Company will be represented at Booth 15 adjacent to one entrance of the scientific exhibit. Northwestern examiners and others who may be interested are cordially invited to visit the booth and meet personally one of the representatives from the home office medical department.

ADVANTAGES OF TAMPAX PRESENTED

Realizing the fact that many physicians are called upon by woman patients to answer questions regarding the different methods of sanitary protection during the menstrual period Tampax Inc. will have an attractive dignified exhibit in Booths 188 and 189 where representatives will be glad to discuss all such problems with visitors. See page 91.

FULL INFORMATION ABOUT 'WIX'

At Booth 212 the Wix Company will give physicians an opportunity to secure full information about Wix tampons. If you have occasion to recommend or answer

questions concerning this newer method of sanitary protection you will want to call and secure the facts concerning Wix. See page 88.

"RADIO NURSE" DEMONSTRATION

An opportunity to see and hear that ingenious new development of science known as the 'Radio Nurse' will be afforded by a visit to the Zenith Radio Corporation Booth 181. The device consists of two small units the 'Guardian Ear' supersensitive to the slightest sound, to be plugged into an electric outlet in the nursery or sickroom and the 'Radio Nurse' proper, which is plugged in wherever the mother happens to be thereby conveying to her the slightest sound—a cry, a cough or even the sound of breathing.

OFFICE FURNITURE

NEW LINE OF WOODEN FURNITURE

Physicians will want to take a few minutes to investigate what is new in office equipment. An entirely new line of physicians' wooden furniture with an abundance of improved time-saving features, will be found on display at Booths 55 and 56. In addition the Allison Company will have on display the popular Hanes table. See page 110.

NEW FURNITURE FOR THE OFFICE

If you have a feeling that your office needs modernization and the installation of new style furniture it will pay you to stop at the exhibit of the Hamilton Manufacturing Company Booths 31 '32 and 33. They show a wide range of styles in modern as well as conservative designs and representatives will be glad to render assistance in your office planning. See page 119.

THE EAR NOSE & THROAT OFFICE

A sample treatment room will be shown by Surgical Mechanical Research in Booth 242. Physicians are invited to visit the display and look it over with such questions as the following in mind: Does it meet my particular needs? 'Will it always look neat and clean? Can I reach everything with a minimum of effort?' (Can I make a complete examination without moving the patient? What will be the reaction of the patient?

OPTICAL INSTRUMENTS

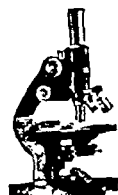

DIAGNOSTIC INSTRUMENTS

American Optical Company will display its varied line of professional diagnostic instruments such as the ophthalmoscope otoscope retinoscope transilluminators diagnostic sets and other ophthalmic instruments and equipment in Booths 201 201-A and 206. In addition it will feature the Ophthalm O-Graph a portable binocular eye movement camera which yields a

visible objective and practical record of the functional efficiency of the reading eyes also the Metron-O Scope, which is a triple shutter short exposure device for orthoptics applied to controlled reading.

NEW CLINICAL MICROTOME

A feature of Bausch & Lomb's exhibit Booths 202 and 232 will be the new clinical microtome for rapid, accurate sectioning of frozen celloidin and paraffin material. A Dubosq biological colorimeter with a new direct reading scale will be shown also various models of Bausch & Lomb's medical research and laboratory microscopes with accessories. Haemocytometers hemoglobinometers slit lamps, the binocular ophthalmoscope, and the stereo camera will be included. See page 115.

THE BIO PHOTOMETER

The physician who has heard of the Bio Photometer for the clinical determination of the vitamin A status of the patient and has desired to obtain first hand information concerning its operation will have an opportunity of so doing at Booth 213. Three different models in which the Bio-Photometer is now available will be shown at an interesting price range, and you are cordially invited to inspect all models at this Prober-Faybor exhibit. See page 78.

KEYSTONE VIEW COMPANY

Keystone View Company will present for the first time the Keystone Tests of Binocular Skill an adaption to the Telebinocular of the Oral Reading Check Tests by William S. Gray. Another 1938 product to be shown is a unit of reading slides in three levels of difficulty especially adapted to all orthoptic exercises requiring sharp fixation. The Synoptoscope and the Keystone series of transparencies for use in Synoptoscope, Synoptophore and Orthoptoscope with a manual and some new techniques with the Telebinocular and Tel Eye-trainer will also be shown. Booth 251.

NEW QUEBEC COLONY COUNTER

The Spencer Lens exhibit will feature medical microscopes equipped for bright field and dark field work also for blood counting with the Bright-Line Haemocytometer. Several types of Spencer microtomes will be set up for demonstration. Delinescopes for the projection of lantern slides filmstrips or opaque materials—instruments for the lecture hall—will be exhibited. The Quebec Colony Counter, a new bacteria viewing device will be shown to Convention visitors for the first time. Booth 228.

ZEISS EXHIBIT

Carl Zeiss Inc. will exhibit at Booths 154 and 155 a collection of Carl Zeiss-Jena instruments such as microscopes microphotographic equipment projection apparatus refractometers ophthalmological instruments contact lenses etc. as well as Zeiss-Ikon cameras, including the Contax. Special attention will be directed to the Wolf-Schandler Flexible Gastroscope and to a new model of the Zeiss Nordenson Retinal Camera. See page 65.

PHARMACEUTICALS and BIOLOGICALS

NEW 'COUNCIL ACCEPTED' PRODUCTS

A feature at the exhibit of Abbott Laboratories in Booths 103 and 104 will be a section displaying more than 35 of their products which have been accepted by the Council on Pharmacy and Chemistry since January 1 1938. Other popular items selected from their long list of Accepted specialties also will be shown. You will be most cordially welcomed by the well trained corps of Abbott representatives who will be glad to discuss these products with you. See pages 30 and 31.

ARLINGTON CHEMICAL EXHIBIT

Physicians desiring to discuss their allergic problems will find cordial cooperation from the representatives in charge of the Arlington Chemical Company exhibit Booth 153. A new diagnostic protein outfit containing 80 units, which was first announced in the March 26 1938 Journal of the A. M. A. will be especially featured, as well as the smaller diagnostic pollen outfits which are made up for individual patients in any area. See page 42.

WILL FEATURE ORGANO-THERAPEUTICS

New products and processes illustrative of the progress and technique in the manufacture of organo-therapeutics will be featured at the Armour Booths 166 and 190. Improvements in packaging and standardization of accepted products as well as many new items, will be exhibited. New dermal and ophthalmic Nu-Grip sutures will also be shown, and practitioners interested in recent developments in hormone therapy and other problems in endocrinology may discuss such matters with the head of the clinical research department. See page 39.

INTRAVENOUS SOLUTIONS

Baxter's line of Intravenous Saline and Dextrose solutions in Vacoliers the vacuum sealed container dispensers will be displayed in Booth 2. Also the Baxter suction siphon, for effective cavity drainage will be shown, as will the Baxter blood transfusion set and 'Blood Bank' assembly.

BILHUBER KNOLL MEDICINALS

Metrazol a restorative in barbiturate or opiate poisoning surgical shock and asphyxia. Dilaudid hydrochloride for pain relief and cough sedation. Theocaine for diuretic and myocardial stimulation. These and the other well known medicinal chemicals of Bilhuber-Knoll—Euresol Lenigallol and Bromural—can be discussed at Booth 96. Helpful prescription data on these products will be available.

SPECIALTIES BY CALCO

Urginin a cardiac drug useful in auricular fibrillation cardiac arrhythmias decompensation myocardial insufficiencies and cardiovascular-renal disorders will be featured at Booth 41 by Calco Chemical Company Inc. also Trichlorethylene-Calco useful in the treatment of burns and other Calco specialties including Aminoacetic Acid (Glycine Glycocol)-Calco Tetrachlorethylene-Calco, Medicinal Dyes.

ANTI-ANEMIC PREPARATIONS

Chappel Laboratories extend an invitation to all members of the medical profession to visit their technical exhibit of Council Accepted anti-anemic preparations including Chappel Liver Extract, Concentrated, Intramuscular, and Chappel Liver Extract Subcutaneous which will be featured as outstanding developments in the potency and purification of Liver Extracts. Booth 151.

SODIUM BICARBONATE U. S. P.

Church & Dwight Co. Inc. invites you to visit Booth 102. Here in a newly designed and very modern exhibit will be shown those dependable old products Arm & Hammer and Cow Brand Bicarbonate of Soda which have stood the 'acid test' of time since 1846 and meet all the requirements of the U. S. P. Competent representatives will be in charge. See page 71.

CIBA PHARMACEUTICAL PRODUCTS

Physicians are cordially invited to visit the Ciba Booths 12 and 13, where they will find exhibits of well known Ciba specialties, among which are Digifoline Dial Nupercaine Lipiodol and Vioform. Uses for these products will be described by the assistant medical director and the representatives of the firm who will be glad to discuss any questions the doctor may have. See page 64.

SHOWN BY CUTTER LABORATORIES

Cutter Laboratories, in Booth 105 will feature their Council Accepted biologicals and allied intravenous specialties. Dextrose solutions in Saffitasks with the various mechanical improvements and modifications developed within the past year will be demonstrated by competent representatives. Of particular interest to visiting physicians will be their display of hy fever treatment sets together with the demonstration of the Cutter antitoxin syringe. See page 62.

VISIT DAVIES ROSE EXHIBIT

When rambling among the scientific and commercial exhibits you will find it pleasant and profitable to visit the Davies Rose & Company booth 172. Here there will be on display preparations of particular interest to cardiologists and neurologists with well informed representatives to explain them and discuss some of the new therapies with you.

PULVOIDS—HYPOLSOLS

One of the many interesting exhibits this year will be at Booth 127, the display of The Drug Products Co. Inc. where representatives will be on hand to explain the extreme care taken in the manufacture of the company's Hypolsols (ampoules) and Pulvoids. The Hypolsols exhibit will stress the fact that these ampoules measure up to rigid U. S. P. and N. F. requirements. Physicians are invited to spend a few moments at this informative booth. See page 76.

RECENT 'ROCHE' CONTRIBUTIONS

The exhibit of E. Rouger & Company, occupying booths 147 and 148 will feature the distinctive contrast medium Lipiodol Lafay. Up to date literature and reports will be available for the visiting physician. See page 46.

LIPIODOL FOR RADIOLOGY

The exhibit of E. Rouger & Company, occupying booths 147 and 148 will feature the distinctive contrast medium Lipiodol Lafay. Up to date literature and reports will be available for the visiting physician. See page 46.

VITAMIN D PRODUCTS DISPLAY

An informative display featuring Vitamin D in the form of Viosterol (A.R.P.I. Process) in Oil for the pharmaceutical trade and Vitamin D incorporated in evaporated milk for the fluid milk dealers, awaits physicians visiting this booth. The story of what the product Embo (Wheat Embryo) can accomplish in cases of Vitamin B deficiency also will be told. Nationally known products of the parent company, General Mills Inc. will be an interesting part of the exhibit. Booth 198.

CALL FOR THIS BOOKLET

Intravenous solutions in Filtraid dispensers will be exhibited at the Hospital Liquids, Inc. display Booth 192. Physicians will find interesting the manner in which solutions are kept pyrogen protected and how they can be depended upon for sterility, security and safety in administration. Copies of an authoritative informative booklet 'Parenteral Administration of Fluids' will be on hand for free distribution. See page 89.

MERCUROCHROME EXHIBIT

Hynson Westcott & Dunning Inc. will have an exhibit featuring Mercurochrome and various pharmaceutical specialties of their manufacture. There will also be a display of some of the diagnostic apparatus and ampule solutions which have been developed in cooperation with physicians. Competent representatives of the company will be in attendance to demonstrate the products and to answer questions. Literature and samples will be available to physicians. Booth 90.

AMPOULE PREPARATIONS

Their Council Accepted Ampoule preparations, particularly their ampoules of Dextrose (d Glucose) 50% Sodium Lactate Calcium Chloride and Mercury Succinimide will be exhibited by Lakeside Laboratories, Inc. in Booth 101. Members of the research staff will be present to demonstrate the chemical bacteriological and physiological methods used to insure their purity, sterility and safety. See page 26.

HOUSE OF VITAMINS

Complete information on all matters pertaining to vitamins will be available for physicians at the International Vitamin Corporation Booth 252. Included will be a showing of the following Council Accepted vitamin products: Hailbut Liver Oil Plain in Liquid and Capsule form.

LIST OF EXHIBITORS

Halibut Liver Oil with Vitamin D Concentrate in Liquid and Capsule form. Cod Liver Oil Concentrate in Liquid and Capsules. Cod Liver Oil Vitamin Concentrate in Tablets and Viosterol (A R P I Process) in Oil. See page 47

FOUR SECTIONAL LEDERLE DISPLAY

The progress and value of modern therapy in the treatment of pernicious anemia, pneumonia and scarlet fever are described in color animation graphs and photo-murals in the new four-sectional Lederle display which will occupy spaces 113 and 114.

114 Descriptive technical information as well as the Lederle products on liver therapy, pneumonia typing and pneumonia sera and treatment and the use of scarlet fever antitoxin for prophylaxis and therapy will be attractively shown. See page 39

DEMONSTRATIONS BY LILLY

In a continuous demonstration Eli Lilly and Company will carry out a method of standardizing oxytocic drugs upon isolated uterine muscle. Especially designed and lighted apparatus will enable the observer to follow the extent and duration of muscle contraction. The display occupying Booths 61 to 64 inclusive will also present new and interesting panels dealing with liver products: Iletin (Insulin Lilly), Protamine Zinc Iletin (Insulin Lilly), Metacaine (Gammay-2 methyl-piperidine) propyl Benzoyl Hydrochloride (Lilly), Ephedrine, and Carbarone. See page 58

MALLINCKRODT CHEMICALS

Physicians and their friends will be welcomed at the Mallinckrodt Chemical Works booth No. 12 where will be exhibited specialties as well as a long line of USP and N F preparations. The central theme will be the English and Latin labeled bottle which recalls the pharmacy of earlier days and which is a step toward raising pharmacy to a higher place in professional esteem. Along with well known prescription items will be shown analytical reagents used in pathology and chemicals used by the various departments in routine hospital procedure. See page 51

COD LIVER OIL RESEARCH

The Maltine Company will demonstrate in Booth 30 the various steps involved in the manufacture of Maltine with Cod Liver Oil and will show illuminated slides of interest to physicians including photomicrographs indicating the minuteness and uniformity of the oil globules in Maltine with Cod Liver Oil

HALIBUT VITAMIN PRODUCTS

McKesson & Robbins Inc will display in Booth 245 a series of halibut liver oil products accompanied by an exhibit which will indicate the effects and use of vitamins A and D in the treatment of conditions arising from a deficiency of either or both of these vitamins

LINDE AIR PRODUCTS TO EXHIBIT

The Linde Air Products Company in conjunction with National Carbon Company Inc another unit of Union Carbide and Carbon Corporation will occupy Booth

81. The exhibit will feature the use of oxygen for therapeutic purposes and the installation of piping systems for more economical distribution of oxygen. Illustrations will show various methods of administering oxygen therapy and oxygen therapy apparatus will be on display

VITAMIN B₁ HYDROCHLORIDE

Merck & Co Inc manufacturers of vitamin B₁ HCl are presenting an exhibit in Booths 10 and 11 devoted to the synthesis the requirements for and the therapeutic uses of this product. The synthesis of crystalline vitamin B₁ HCl was followed by its successful production on a commercial scale. With adequate quantities available extensive clinical studies were made possible. All physicians attending this convention are cordially invited to visit this exhibit. See page 32

TO SHOW COLORFUL DIORAMAS

Only a five minute visit at Booth 59 is necessary to view an interesting series of colorful dioramas depicting a variety of subjects and scenes from several parts of the world—cod fishing off Norway, shipping castor beans from inland Brazil and birch-brush harvesting in the New England hills. Two contrasting scenes—one showing the typical mid-west apothecary of the early nineteenth century and the other a section of a present-day research laboratory—help to illustrate the great progress of pharmacy during the past century. See pages 28 and 38

PARKE DAVIS EXHIBIT

A number of scientific accomplishments will be displayed by Parke Davis & Company's staff of expert technical men in charge of Booths 91 and 92. Products of special interest to the medical profession will be shown including Mapharsen (an advance in antisyphilitic therapy), glandular products (Theelin, Adrenalin and the Pituitrin group) also Meningococcus Antitoxin and other biological products

GET YOUR COPY OF 'HABIT TIME

Doctors who visit Booths 58 and 205 will be interested in the new and revised edition of Petrolagar's Habit Time booklet which has just come off the press. In addition to a wealth of information on the subject of constipation, Habit Time contains a number of splendid anatomical drawings by the celebrated Tom Jones. There will also be available a few sets of the Nineteenth Century Types caricatures of famous men of science lithographed and mounted for framing. These will be supplied to physicians as long as the limited supply lasts. See pages 36 and 37

FOR BILIARY TRACT DISORDERS

At Booth 34 Riedel-de Haen Inc will display the advantage of prescribing chemically pure bile acids and their sodium salts in the treatment of hepatic and biliary tract disease. Well informed representatives will gladly furnish any information regarding Decholin and Decholin sodium. Also on display will be Penoston a safe and dependable hypnotic. See page 44

SHOWN FOR THE FIRST TIME

At the Rare Chemical Booth No. 3 the following preparations will be featured: Gitalin (Amorphous) a rapid dependable glucosidal fraction of digitalis purpurea, which while as economical and effective as most whole leaf preparations, possesses a

more uniform rate of elimination, Salysal "Rare Chemicals," the salicylic ester of salicylic acid which provides improved salicylate therapy because local gastric irritation is reduced to a minimum and a smaller dosage is necessary, and Optochin Hydrochloride ethylhydrocupreine a specific for pneumococcal infections of the eye

SANDOZ PHARMACEUTICALS

Sandoz Chemical Works will show their "Council Accepted" specialties in Booth 67. Products to be featured are Gynergen widely prescribed for the dramatic relief of migraine sufferers and for uterine hemostasis, the gluconate preparations of calcium (Calglucon) for oral intramuscular and intravenous calcium therapy, "Scillaren" and Scillaren-B time-tested cardiotonics, "Sandoptal," isobutylallyl derivative of barbituric acid

SCHERING EXHIBIT

Schering Corporation will have a new attractive exhibit in Booth 112. Members of the medical profession are cordially invited to call. Here will be an opportunity for personal discussion with representatives of the medical division and research laboratories concerning latest therapeutic developments. See page 36

SEARLE PREPARATIONS

Valuable contributions to modern therapy will be displayed by the research laboratories of G D Searle & Company. Every physician is invited to call at Booth 65, where such products as Aminophyllin (Searle) and Aqueous Bismuth Sodium Tartrate will be shown. Capable representatives of the medical service department will be on hand to welcome you and furnish any desired information

STRIKING SHARP & DOHME DISPLAY

Sharp & Dohme will have a new display at Booths 79 and 80. A number of items will be interestingly featured including digitalis capsules, Propadrine Hydrochloride products and Protamine Zinc Insulin. Included will be a continuous showing of moving pictures on Antivenin and Protamine Zinc Insulin. Competent well-informed representatives will be on hand to welcome physicians and to furnish information on Sharp & Dohme products. See page 33

NUTRITIONAL SPECIALTIES

Smaco Nicotinic Acid (3 Pyridine Carboxylic Acid) the factor of the vitamin B complex now being used for clinical research in connection with pellagra will be displayed by S M A Corporation in Booth 186. Other nutritional specialties exhibited will be Smaco Carotene-(Provitamin A) in capsule, liquid form plain and combined with vitamin D-concentrate, Hypo-Allergic Milk, Alerdex the Protein Free Maltose and Dextrins, Protein S M A (Acidulated) and S M A the antirachitic, antispasmodic breast milk adaptation. See third cover

Please send in promptly notice of change of address giving both old and new always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, MAY 7, 1938

THE SAN FRANCISCO SESSION

It is fifteen years since the American Medical Association last held an annual session in San Francisco. At that time the membership of the Association was 88,519, today it is 109,435, the largest number ever recorded in the history of the organization. Hygiene had just been established and is now celebrating its fifteenth anniversary, with a circulation well over 100,000. A few of the state medical societies had begun efforts for postgraduate education of their members, today we publish, week by week, records of the extension of this work to practically every state in the union. Fifteen years ago the American Medical Association was publishing five special periodicals, today there are nine, including the *Quarterly Cumulative Index Medicus*. There had not been established the Council on Foods, the Bureau of Medical Economics, the Bureau of Exhibits, the Bureau of Health and Public Instruction, the Council on Industrial Health and the Council on Physical Therapy. Since that time the American Medical Association has built a new building for its headquarters office. The number of employees has increased from 365 to 615. These simple facts indicate to some extent the expansion in the activities of the American Medical Association.

Next let us consider the problems that concerned the organized medical profession in 1923. The speaker of the House of Delegates called for a campaign against the socialization of medicine and urged the development of a department of health in the cabinet. These messages were reiterated by the President of the Association, Dr. George E. de Schweinitz. The President-Elect, Dr. Ray Lyman Wilbur, urged the establishment of a board of strategy in the American Medical Association which would be planning from five to ten years ahead for the work of the organization. The House of Delegates concerned itself with problems related chiefly to medical education, the abuse of clinics and the conduct of the affairs of the organization. There was much agitation concerning the lawful or unlawful prescribing of alcoholic liquors. Moreover, it was moved to create a section on radiology for the scientific advancement of

that specialty. The Scientific Assembly concerned itself with symposiums on diet, on the mental health of the child and on preventive medicine. At the San Francisco session of 1923 Dr. William Allen Pusey was made President-Elect.

A reference to the report of the Board of Trustees and to the reports of officers, published in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* last week, and to the preliminary programs for the San Francisco session, which appear in this issue, indicate the advances that have taken place during fifteen years. The medical profession still maintains its successful opposition to socialization or federalization of medical care. It is now embarked on a nationwide program for the study of medical care and extension of medical service. This campaign, in the interest of the American people, has been one of the main problems before the American medical profession during this period. The new councils and bureaus indicate how completely the Association has accepted its responsibility in relationship to the care of the people's health. New methods of living and new problems of our civilization become promptly the concern of the American medical profession.

Attention should be called specifically to the program of the General Scientific Meetings, which appears on page 1574. At the time of the previous San Francisco session there was no such elaborate planning for carrying to the medical profession, through the clinical lectures, the latest advances in various fields. The special symposium on health problems in education is an indication of the manner in which the medical profession is cooperating with the schools in recognition of the fact that health must be the first objective in all education. The special symposiums that have been arranged in the various sections are a further indication of present interests, including particularly those concerned with the blood dyscrasias, the newer methods of treatment of schizophrenia, the occupational dermatoses, and infections of the sinuses. The Scientific Exhibit, described on page 1588, will reveal special sections devoted to anesthesia and to fractures, with innumerable exhibits in which men who have developed new methods in diagnosis, treatment and prevention of disease will themselves demonstrate the details of their work.

The annual session of the American Medical Association has become the leading event of the medical year, attracting from 6,000 to 10,000 physicians and representing every phase of medical interest. There is no reason to doubt that the San Francisco session will this year constitute the greatest medical assemblage ever held on the Pacific coast.

Already the demand for rooms is so great that many of the leading hotels are placed under considerable pressure. If you are planning to come to San Francisco, write at once, using the coupon on page 90 of this issue of *THE JOURNAL*, so that a suitable room may be found for you.

THE NATURE OF XANTHOMATOSIS

Xanthomatosis has for many years been a condition of obscure etiology. Most observers agree that the syndrome xanthomatosis is a manifestation of disturbed lipid metabolism. Many unsolved questions remain with regard to the lipid metabolism itself and its relation to the general metabolism. No doubt xanthomatosis includes a number of heretofore unrelated clinical conditions. First it was described as a rare disease of the skin. The commonly seen lesion is the familiar orange-yellow plaque on the eyelids of persons past middle life. The lesions are not confined to the skin but are observed in connection with tendon sheaths, mucous membranes, the heart, the peritoneum, the liver, the spleen and other internal organs. The lesions appear as plaques or nodules of a striking sulfur yellow to yellow-brown. The characteristic microscopic feature is the presence of large bright polyhedral cells with vacuolated or "foamy" protoplasm due to the high content of a fatlike substance. With the discovery by Panzer in 1906 and by Pinkus and Ludwig Pick in 1908 that the fatlike substances in the xanthomatous lesions were doubly refractile lipoids, the concept was formed that these lesions resulted from a disturbance of lipid metabolism. Aschoff's demonstration of the selective affinity of the macrophages for various dyes as well as for fat substances made it possible to regard the foam cell as a cell of the reticulo-endothelial system, infiltrated with lipoids. Rowland¹ suggested that xanthomatous lesions represent a hyperplastic reaction of the reticulo-endothelial system resulting from infiltration of lipoids in excess in the body fluids. Xanthomatous lesions then represent an attempt to rid the body fluids of lipoids which cannot be properly excreted and which act as an irritant. Rowland proposed the name xanthomatosis to include the various manifestations related to disturbed lipid metabolism.

Pinkus and Pick have demonstrated that the fat substances in the xanthomatous lesions are the doubly refractile lipids, cholesterol and cholesterol esters. They believed that certain cells became infiltrated with cholesterol because of an increased supply from the blood. This concept was supported by Aschoff's demonstration that reticulo-endothelial cells were able to take up certain dyes and fatlike substances from the blood.

Antschkow in his cholesterol feeding experiments was able to produce foam cells in rabbits. It appeared, therefore, that hypercholesteremia was a necessary condition for the product of xanthomatosis. Chauffard and Laroche actually demonstrated the existence of hypercholesteremia in patients with xanthoma. They saw an analogy between the xanthomatous nodules due to excess of cholesterol in the blood and the tophi of

gout due to the excess of uric acid in the blood. Later investigators found that cholesteremia does not always result in xanthoma eruption. Clinical observations suggest that trauma, friction or infection may act as accessory factors in producing these lesions.

Thannhauser and Magendantz² insist that there is no proof of the existence of such a disease as a general metabolic disturbance of the cholesterol metabolism and suggest that the metabolic disturbance in question is an intracellular disturbance confined to the reticular cells themselves, in consequence of which they may become xanthoma cells not by an increased supply but as the result of an intracellular metabolic disorder. These authors point out that hypercholesteremia is found only in one group of xanthomatous organs while the other shows a normal amount of cholesterol in spite of the fact that the same histologic constituents are found in the two. This, in their opinion, favors the idea that one has to deal here with a local cellular disturbance rather than with a general metabolic disturbance of cholesterol synthesis. They regard xanthoma cells as fat cells with embryonal qualities able to form all kinds of lipids.

Whether the xanthoma cells represent an infiltrative, a chemical or a degenerative process, it is apparent that the disturbance of lipid metabolism of the reticulo-endothelial system is the underlying pathogenesis in a number of hitherto unrelated clinical entities. Among these should be included xanthelasma palpebrarum, xanthoma multiplex, xanthomatous tumors of tendon sheaths and generalized visceral xanthomatosis, including such apparently distinct entities as the Schuller-Christian syndrome, Niemann-Pick disease and Gaucher's disease.

GRADUATE INSTRUCTION IN COUNTY SOCIETIES

Thirty-five years ago Sir William Osler¹ spoke on the educational value of the medical society. A well conducted medical society, he maintained, should represent a clearing house in which every local physician would obtain his intellectual rating and in which every physician could determine his assets and liabilities. "We doctors do not 'take stock' often enough," said Osler, "and are very apt to carry on our shelves stale out-of-date goods. The society helps to keep a man up to the times" and enables him to refurnish his mental shop with the latest wares. It keeps his mind open and receptive and counteracts that tendency to premature senility which is apt to overtake the man who lives in a routine."

The American Medical Association was founded primarily to cultivate and advance medical knowledge.

1 Osler William. On the Educational Value of the Medical Society. Boston M. & S. J. 148: 275 1903.

As a federation or union of constituent societies, it looks largely to its county and state organizations to share the responsibilities which were assumed ninety-one years ago. These component societies have not been unmindful of their duties. In many communities they have successfully conducted postgraduate extension courses and have made this work their most important function.

As early as 1906 the Tarrant County Medical Society of Texas had, under the stimulus of Dr J. N. McCormack, field organizer of the Association, offered twelve courses of from five to fifteen periods each on such subjects as anatomy, bacteriology, pathology, pharmacology, physiology, physical diagnosis, medical jurisprudence, history of medicine and surgery. In the next year Dr John H. Blackburn of Bowling Green, Ky., outlined a four year course of study for physicians in the Councilors Bulletin of the American Medical Association, which was distributed to officers of county and state societies throughout the country. This systematic, continuous review of what was essentially the undergraduate curriculum was a forerunner of the postgraduate plans now operating so successfully in such states as Michigan, Ohio and California. The importance of presenting clinical material for discussion was appreciated then as now. Graphs, charts and other adjuncts to informal discussions were definite aids to teaching. By 1909 approximately 350 county societies in twenty-nine states were actively participating in the American Medical Association's program.² A second four years of general review courses was given from 1911 to 1915, at which time the Council undertook its first survey of graduate medical education. Seven years later the Council again encouraged every county medical society to engage in an educational program. While it was appreciated that this was a national, a state, a community problem, it is always, in its practical application, a community problem.³ At that time it was recommended that a plan of postgraduate lectures and diagnostic clinics be provided. In the next year, 1923, the President-Elect of the Association, Dr Ray Lyman Wilbur, stated that each state organization must recognize its responsibilities and take the initiative in meeting its local conditions and that each state should be urged to work out its own problems in its own way. President George E. de Schweinitz (1922) had likewise recommended that the Association should expend greater energy, especially through the state and county medical societies, in this connection. The Council on Medical Education and Hospitals was urged to take up and promote postgraduate medical education in county and district medical societies. At this time a set of principles concerning graduate medical education was adopted by the Council and endorsed by the House of Delegates.

Subsequent reports by Dr. Olm West, Secretary of the Association, have indicated the increasing interests and demands of physicians for continuing training after licensure. Such efforts, stimulated by the Council, must originate locally. Frequently the hope has been expressed that a way might be found by which the American Medical Association could become actively helpful in providing clinical instruction for its members who could not avail themselves of the facilities at medical centers far removed from their homes. The survey now being conducted by the Council on Medical Education and Hospitals will indicate what has been done and also the places where help may be needed.

DEATHS FOLLOWING ELIXIR OF SULFANILAMIDE-MASSENGILL VI

The investigation of the deaths following the use of Elixir of Sulfanilamide-Massengill, as was brought out in the reports of officers and the Board of Trustees, published last week, was a noteworthy example of the work of the headquarters group of the American Medical Association for the protection of the public.¹ In this work Drs. E. M. K. Geiling and Paul Cannon and their associates at the University of Chicago gave indispensable cooperation. As soon as possible after notification of apparent toxic actions following the use of this preparation was received, reports were published pointing out that diethylene glycol was the toxic agent. The number of deaths that were confirmed was seventy-six, others were reported to the government.²

Approximately six months has elapsed since this disaster. Now Drs. Paul R. Cannon and E. M. K. Geiling³ have published some further studies of pathologic effects, in both experimental animals and man, of Elixir of Sulfanilamide poisoning. The pathologic effects in the kidneys and livers of dogs, rats and rabbits were identical when comparable amounts of Elixir of Sulfanilamide or pure diethylene glycol alone were administered by mouth, in divided doses. When diethylene glycol, the solvent for sulfanilamide in the "Elixir," was excreted through the kidneys of the experimental animals, severe hydropic degeneration of the convoluted tubules occurred and also occlusion of the lumens. As a consequence, anuria resulted followed by acidosis and uremia. The diethylene glycol also caused a characteristic central hydropic degeneration within the liver. Essentially similar changes were observed in the kidneys and livers in necropsy material examined by them from eleven human fatal cases of poisoning by "Elixir of Sulfanilamide." Pulmonary

2. Personal communication from Dr. John H. Blackburn.

3. Minutes of the Annual Meeting of the House of Delegates of the A. M. A. St. Louis 1922 p. 29 (Dr. A. D. Bevan, chairman, Council on Medical Education and Hospitals).

edema and at times bronchial pneumonia developed in both the experimental animals and in human beings. In several of the human cases diffuse symmetric cortical necrosis with recent hemorrhages was present in the kidneys, resembling in many respects the symmetric cortical necrosis that is observed in some of the toxemias of pregnancy. Hyaline thrombosis of the smaller cortical arteries and arterioles with resulting diffuse infarction of the cortex was noted. Essentially identical changes were described by Barber in five fatal cases of poisoning by dioxane, the anhydride of diethylene glycol.⁴

In common with other glycols, such as glycerin, diethylene glycol is a hygroscopic agent. It is not metabolized, apparently, and, according to Cannon and Geiling, may accumulate in the cells of the convoluted tubules causing them to hold more water. Its effect, they point out, may be due to cytoplasmic injury of the tubular cells with resulting disturbance of internal metabolism and severe intracellular edema. Sulfanilamide alone does not cause these results in dogs, rabbits or rats, even when given in large doses.

Several interesting pharmacologic points arise from the work necessitated by the "Elvair of Sulfanilamide-Massengill" tragedy. One emphasizes anew that acute toxicity alone is not an adequate criterion for evaluating the safety of a drug, determinations of chronic toxicity are equally important. In all cases careful pathologic studies are desirable. In work dealing with drug tolerances and toxicity, observations should be made on different species. Further experimental studies concerning the toxic effects of other glycols are under way which will lead to better understanding of this class of compounds.

Current Comment

PRESENT TRENDS OF FATALITY IN PULMONARY TUBERCULOSIS

Although the incidence of pulmonary tuberculosis has been decreasing in this country for a number of years, the effectiveness of present day methods of therapy is not equally well understood. Recently Drolet¹ has analyzed the case fatality rates from 1915 to 1935. The ratio of deaths to new cases of tuberculosis in the various communities has varied little during the past twenty years. During the period in which the incidence of the disease and the mortality have declined from 40 to 60 per cent, the ratio of deaths to new cases has declined only 5 or 6 per cent in New York, Detroit and Philadelphia, in Chicago there has been no decrease. Persons dying from tuberculosis now, however, average a slightly greater age than formerly. In the United States the average age of death of males was 36.4 years in 1913 and 41.5

years in 1933, in females it was 32.5 in 1913 and 35.8 in 1933. Similar increases in average age were noted in statistics from England and Wales. In the United States among patients in sanatoriums the death rate was 20 per cent in 1925, 23 per cent in 1931 and 24 per cent in 1934. The proportion of all tuberculous patients "isolated" in hospitals, however, is several times greater now than in the past and has risen from approximately 4 per cent in 1915 to 25 per cent in 1934. The adjustment of these figures indicates that sanatorium and surgical treatment of pulmonary tuberculosis have had little effect on the case fatality rates of the tuberculous population in the communities studied. This constitutes a surprising statistical conclusion in view of the apparent individual effectiveness of such measures as pneumothorax. Further analytic studies should be made before it can be safe to conclude that therapeutic measures in pulmonary tuberculosis are as ineffective as they appear to be statistically.

Association News

RADIO BROADCASTS

The American Medical Association and the National Broadcasting Company present the fifth series of network health programs, beginning Oct. 13, 1937, and running weekly through June 15, 1938. The programs are presented over the Red network each Wednesday at 2 p. m. eastern standard time, 1 p. m. central standard time, 12 o'clock noon mountain standard time and 11 a. m. Pacific standard time.

In localities where daylight saving is in effect the schedule remains the same but this brings the program one hour earlier to adjacent areas on standard time.

The hours indicated above will be effective until June 1. Programs for June 1, June 8 and June 15 will be broadcast at 12:30 p. m. eastern standard time or 1:30 eastern daylight saving time, central time is one hour earlier, mountain time two hours earlier and Pacific time three hours earlier than eastern daylight saving or standard time.

The dates and topics of the broadcasts for the next five "Your Health" programs are as follows:

Mothers and Children

- May 11—Hospitals Aid Health: the place of the hospital in the health program of the individual and the community.
May 18—Runabouts, 1938 Model: the preschool child and the health and personality problems of that age.

Using Health Knowledge

- May 25—The Health Check-Up: periodic health examination and what follows, and why.
June 1—Vacation Plays and Misplays: making the vacation a real contribution to health and recreation.
June 8—Graduation and Then: What a new phase of life begins at commencement, and health contributes to success.

The stations on the Red network are privileged to broadcast the program, but since it is a noncommercial program they are not obliged to do so. Interest on the part of medical societies, women's auxiliaries and others may have weight with program directors of local stations. A personal visit to the program director might be advisable if the program is not being taken by a local station. This is an opportunity for the appropriate committees of county medical societies to indicate their interest in having this program broadcast in their community and to enlist the interest of other groups.

CALIFORNIA

The Herzstein Lectures—Dr George W. Pickering, department of clinical research, University College Hospital Medical School, London, England, will deliver the sixth course of the Morris Herzstein Lectures in San Francisco, under the auspices of Stanford University and the University of California. Following are the dates and titles of the lectures:

- May 23 The Problem of High Blood Pressure in Man
- May 24 Experimental Hypertension
- May 25 The Renal Pressor Substance

Dr Pickering will also give a popular lecture at a luncheon May 26 on "The Biological Significance of Pain."

FLORIDA

State Medical Meeting at Miami—The sixty-fifth annual meeting of the Florida Medical Association will be held at the Columbus Hotel, Miami, May 9-11, under the presidency of Dr Edward Jelks, Jacksonville. The Dade County Medical Society will act as host. The speakers will include:

- Dr Harrison A. Walker, Miami Beach: Preoperative and Postoperative Care in Intestinal Obstruction
- Dr Luther W. Holloway, Jacksonville: Quinine Blindness in Children
- Dr Carol C. Webb, Pensacola: Hand Infections
- Dr Milton Paul Travers, Miami Beach: Frequent Causes of Prolonged Disability in Fracture Treatment
- Dr Aubrey L. Huskey, Chattahoochee: Insulin Shock Therapy
- Drs Robert E. Repass and Carl S. McLeMORE, Miami Beach: Relation ship of Carcinoma of the Larynx to Precancerous Lesions
- Dr Orville N. Nelson, Bay Pines: Management of Sinusitis
- Dr James L. Borland, Jacksonville: Diagnosis and Treatment of Amebic Dysentery
- Dr John R. Boling, Tampa: Presacral Nerve Resection for the Relief of Pelvic Pain
- Dr Samuel Marion Salley, Miami: Disturbances of Cardiac Rhythm
- Dr James G. Lyerly, Jacksonville: Prefrontal Lobotomy for Involuntary Melancholia
- Dr Albert B. McCreary, Jacksonville: Final Responsibility of Public Health Rests on the Medical Profession
- Dr Lauren M. Sompayrac, Jacksonville: Lupus Erythematosus
- Dr Jess V. Cohn, Hollywood: Adolescent Turmoil: Agitated Depression with Panic Reaction
- Dr Carl D. Hoffman, Orlando: Sterility

Dr Warren F. Draper, assistant surgeon general, U. S. Public Health Service, Washington, D. C., will address a public meeting in Bay Front Park Monday evening. Golf and fishing are features of the entertainment program, the association dinner will be held Tuesday evening and the annual smoker Monday evening. Associations meeting concurrently with the state society include the Florida Railway Surgeons' Association, the Florida Society of Dermatology and Syphilology, Florida section, Southeastern Surgical Congress, the Florida Pediatric Society and the Florida Radiological Society. A program for women has also been planned under the auspices of the auxiliary to the Dade County Medical Society.

ILLINOIS

State Medical Meeting at Springfield May 17-19—The ninety-eighth annual meeting of the Illinois State Medical Society will be held at the Knights of Columbus Building, Springfield, May 17-19, under the presidency of Dr Rollo K. Packard, Chicago. Dr Irvin Abell, Louisville, Ky., President Elect of the American Medical Association, will deliver the oration in surgery Wednesday May 18 on "Breast Tumors." Out of state speakers will include Drs Elmer L. Sevringhaus, Madison, Wis., on "Pituitary Therapy in General Practice," and Albert D. Ruedemann, Cleveland, on "Exophthalmos." The program will include symposiums on intestinal obstruction, diseases of the respiratory tract, injuries of the abdomen and treatment of malignant disease. Other speakers will include:

- Dr Arthur I. Goodyear, Decatur: Sulfanilamide—Its Use in General Practice
- Dr Abraham A. Low, Chicago: Metrazol Shock Treatment of Functional Psychoses
- Dr Tell Nelson, Chicago: Relation of Allergy to Diseases of the Respiratory Tract
- Dr Harry Culver, Chicago: Traumatic Lesions of the Male Urethra
- Dr Edmund P. Haller, Decatur: X-Ray Therapy of the Uterus and Adnexa

A conference on diseases of children will be held Tuesday morning, consisting of a symposium on the newborn. The annual secretaries' conference will be held Tuesday morning and the annual meeting of the woman's auxiliary on Monday, Tuesday and Wednesday.

Chicago

Testing Stations for Venereal Diseases—The department of health opened on a permanent basis thirty-six neighborhood testing stations for syphilis April 11. In addition there are welfare stations and park district fieldhouses to take care of volunteers who wish to undergo these tests. Since Nov. 30, 1937, the board of health has tested 19,872 volunteers and found 904, or 4.5 per cent infected. Of 6,566 high school children, sixty-one, or 0.9 per cent, were found to be infected, newspapers reported.

Dr Schiller Appointed Pathologist at Cook County Hospital—Dr Walter Schiller, pathologist at Jewish Memorial Hospital, New York, has been appointed chief of the pathology department at Cook County Hospital to succeed the late Dr Richard H. Jaffe. Aged 50 and a native of Vienna, Dr Schiller graduated at the University of Vienna in 1912. He has served as assistant pathologist of the Military Hospital, Vienna, resident pathologist of the Clinic of Internal Medicine and for fifteen years as assistant to the Second Gynecologic Clinic and director of laboratories.

MICHIGAN

Personal—Dr Thomas E. Gibson Paw Paw has been appointed health director of Van Buren County; he held a similar position in Eaton County.—Dr Richard M. Johnson has been appointed medical director of Eloise Hospital, Detroit.

Conference on Mental Hygiene—The Michigan Society for Mental Hygiene held its second annual spring conference at the Hotel Statler, Detroit, April 7-8. The following were on the program:

- Dr John M. Dorsey, Ann Arbor: Intelligent Home Living
- Dr George S. Stevenson, New York: What Constitutes a Good Child Guidance Clinic
- Dr Harry Stack Sullivan, New York: Application of the Principles of Mental Hygiene to the Practice of Medicine
- Dr Henry C. Schumacher, Cleveland: Human Relations in the Business World
- Charles Scott Berry, Ph.D., Columbus, Ohio: What Has Mental Hygiene to Offer to Special Education
- Dr Bernard Gluck, New York: Contemporary Issues in the Relationship Between Psychiatry and the Law

NEW HAMPSHIRE

State Medical Meeting at Manchester—The one hundred and forty-seventh annual meeting of the New Hampshire Medical Society will be held in Manchester May 17-18 at the Hotel Carpenter under the presidency of Dr Samuel T. Judd, Portsmouth. Guest speakers will be:

- Dr John H. J. Upham, Columbus, Ohio: President American Medical Association: Blood Dyscrasias
- Dr Frederick T. Lord, Boston: Treatment of Pneumonia
- Dr Donald S. King, Boston: Cancer of the Lung
- Dr Edward D. Churchill, Boston: Emphysema
- Dr Isidor S. Rabin, Philadelphia: Surgical Diseases of the Extrahepatic Bile Ducts
- Dr Hayes E. Martin, New York: Diagnosis and Treatment of Intra-Oral Cancer
- Dr Walter Bauer, Boston: Treatment of Arthritis

New Hampshire physicians will conduct round table conferences Tuesday and Wednesday mornings. Dr Upham and Dr Ladd will speak at the annual banquet Wednesday evening. At this meeting fifty-year medals will be presented to Drs Aloha H. Harriman, Laconia; Frederick L. Hawkins, Meredith; and Henry O. Smith, Hudson.

NEW JERSEY

State Medical Meeting at Atlantic City—The annual meeting of the Medical Society of New Jersey will be held at the Ambassador Hotel, Atlantic City, May 17-19. There will be a general scientific session Tuesday evening May 17 with Dr George W. Crile, Cleveland, as the speaker on "Clinical Results in the Surgical Treatment of Essential Hypertension." Guest speakers at the section meetings include:

- Dr George B. Easterman, Rochester, Minn.: Newer Aspects in Etiology and Treatment of Ulcer of the Gastrointestinal Tract
- Dr Toufic Nicola, New York: Recurrent Dislocation of the Shoulder
- Dr Thomas H. Lanman, Boston: Surgery in the Abdomen in Infancy and Childhood
- Dr Meredith F. Campbell, New York: Pathology and Treatment of Urinary Infection in Children
- Dr Josephine B. Neal, New York: Treatment of Infections of the Central Nervous System with Special Reference to Sulfanilamide
- Dr George T. Pick, New York: The Clinical Medical of Contact Dermatitis
- Dr Leonard H. Nichols, Cleveland: The William C. Herriman Lecture: Partial and Complete Uteral Obstruction as a Reproductive Problem
- Dr Harvey B. Matthews, Brooklyn: Hemorrhages of Internal Origin
- Dr Leroy A. Schell, Boston: Diagnosis and Treatment of Malocclusion of the Jaws
- Dr Arthur M. Fishberg, New York: Recognition of Early Signs of Heart Failure Frequently Overlooked

NEW YORK

Society News—Dr Isaac H Levy, New York, addressed the Cortland County Medical Society March 18 on 'Lesions of the Opening of the Stomach'—Dr Delmas K Kitchen, Detroit, addressed the Chautauqua County Medical Society March 16 on recent advances in the use of endocrine products—Dr William T Doran, New York, addressed the Fulton County Medical Society Gloversville, March 18 on "Intra-Abdominal Conditions Due to Trauma"—Drs Edward E Gillick, Niagara Falls, and Burton T Simpson, Buffalo, addressed the Niagara County Medical Society, Niagara Falls, March 8 on "Control of Syphilis" and "Recent Advances in the Etiology of Cancer" respectively—Dr Ralph Pemberton, Philadelphia, addressed the Medical Society of the County of Westchester, April 19, on arthritis—Dr Soma Weiss, Boston, addressed the Rochester Academy of Medicine April 7 on Syncope, Shock and Collapse"

New York City

Harlow Brooks Lecture—The Washington Square Medical Society has established the Harlow Brooks Memorial Lecture in memory of the late Dr Brooks, who was a member of the society Dr Emanuel Libman gave the first lecture April 26 on 'Diagnostic Studies in Pain with Special Reference to Abdominal Disorders'

Centennial of Dr John Shaw Billings—The one hundredth anniversary of the birth of Dr John Shaw Billings, under whose direction the Army Medical Library was developed and the *Index Catalogue* was compiled, was observed by a special exhibit at the New York Public Library, of which he was director after his retirement from the army library in 1895 Dr Billings was a surgeon during the Civil War and in 1864 was transferred to the office of the surgeon general The exhibit in his honor, which was mainly biographic, was on view during the week of April 12

Prize for Research on Kidney Diseases—The New York Academy of Medicine announces that approximately \$1,000 is available under the Edward N Gibbs Memorial Prize toward original research on diseases of the kidney during 1938 Candidates must be physicians who have been graduated at least three years and be residents of the United States They shall submit 'evidence of research already performed and of facilities to prosecute research upon the causation, pathology and newer methods of treatment of diseases of the kidney' The award may be continued through not more than three years to any one person Applications with the required evidence should be addressed to the academy, 2 East One Hundred and Third Street, before June 1

Benjamin White Dies—Benjamin White, Ph D, for many years a bacteriologist in New York and Massachusetts, died March 28 in Southern Pines, N C, aged 59 After receiving his doctorate from Yale University in 1903 Dr White was appointed assistant director of the Hoagland Laboratory, Brooklyn and became director in 1907 From 1914 to 1920 he was assistant director of the bacteriologic laboratory of the New York City Department of Health In the latter year he became director of the division of biologic laboratories, Massachusetts Department of Health, where he remained until his retirement in 1933 because of ill health Since his retirement he had completed a book on 'The Biology of the Pneumococcus' sponsored by the Commonwealth Fund of which he was a consultant He was an honorary fellow of the Massachusetts Medical Society and a member of many scientific societies and of the editorial board of the *New England Journal of Medicine* During the World War he served as a captain in the Sanitary Corps, U S Army

OKLAHOMA

State Medical Meeting at Muskogee—The forty-sixth annual session of the Oklahoma State Medical Association will be held in Muskogee May 9-11, with headquarters at the Severs Hotel and under the presidency of Dr Samuel A McKeel Ada Guest speakers will address two general sessions as follows

Dr Frank C Neff Kansas City Mo Management of the Hypertensive Period of Early Infancy Observations from the Current Year's Experience with Medical Cases in a Children's Hospital
Dr William S Middleton Madison Wis The Surgery of Pulmonary Tuberculosis from a Medical Standpoint Acute Coronary Occlusion
Dr Edward H Ochsner Chicago The Middle Way The Socialization of Medicine

In addition, Dr Alexander Marble, Boston will address the section on general medicine on Diabetes Mellitus—Recent

Advances in Its Treatment' and Dr Roland M Klemme, St Louis, the section on general surgery on "Diagnosis and Treatment of Trigeminal Neuralgia" The section on genito-urinary diseases and syphilology will present a symposium on gonorrhea given by Drs Robert H Akim, Oklahoma City, Julius H Howe, Ponca City, and Allen R Russell, McAlester The same section will sponsor a symposium on syphilis given by Drs David V Hudson and James Stevenson, Tulsa, Charles R Rayburn, Norman, and Charles M Pearce, Oklahoma City The annual golf tournament will be held Monday May 9 at the Muskogee Country Club The president's reception and dance will be Tuesday evening The Woman's Auxiliary will hold its meeting Monday

SOUTH CAROLINA

State Medical Meeting at Myrtle Beach—The ninetieth annual meeting of the South Carolina Medical Association will be held at Myrtle Beach May 17-19 with headquarters at the Ocean Forest Hotel The scientific program will open with a symposium on traumatic surgery Tuesday evening May 17, presented by Drs Julian Deryl Hart, Durham, N C, James C McLeod, Florence, Austin T Moore, Columbia and James R Young, Anderson An innovation this year will be round table discussions each afternoon Dr Oren Moore, Charlotte, N C, will conduct one of these on "Office Gynecology" and Dr Richard Torpin, Augusta, Ga, one on obstetrics Dr Isaac A Bigger, Richmond, Va, will deliver the annual oration on surgery on "Indications for Surgical Treatment and Lesions of the Pericardium and Heart" Among South Carolina physicians who will participate in the program will be

Dr George H Bunch Columbia Acute Perforation of Gastric and Duodenal Ulcers
Dr William Weston Jr Columbia Congenital Vomiting—Cause and Treatment
Dr William R Bairon Columbia My Conclusions from Six Years Experience with Transurethral Surgery of the Prostate
Drs Lester A Wilson and Arthur L Rivers Charleston Eclampsia

The South Carolina X-Ray Society will hold its annual meeting May 18 in Myrtle Beach, with James L Weatherwax, A M, University of Pennsylvania, Philadelphia, as the guest speaker

TENNESSEE

State Society Election—Dr Tom R Barry, Knoxville, was elected president of the Tennessee State Medical Association at the annual meeting in Nashville April 12-14 Vice presidents elected were Drs William S Rude, Ridgetop, William A Garrott, Cleveland, and John Jackson, Dyer Next year's session will be in Jackson

Personal—Dr William J Murphy, Kingsport, assistant health officer of Sullivan County, has been appointed to the staff of the state department of health for work in venereal disease control, newspapers have reported—Dr Kendall B Corbin, Stanford University, Calif, has been appointed associate professor of anatomy and histology at the University of Tennessee School of Medicine, Memphis

WASHINGTON

Society News—A program on tuberculosis was presented before the King County Medical Society, Seattle, April 18 by Drs Armin C Rembe, Byron F Francis, Harold E Nichols and Herbert L Hartley—Drs Bernard P Mullen and John A Duncan Seattle, addressed the Chelan County Medical Society March 9 on Management of Abdominal Adhesions and 'Nonpenetrating Abdominal Injuries' respectively—Drs Homer D Dudley, Seattle, and John C Lyman, Walla Walla addressed the Spokane County Medical Society, Spokane, April 14 on Treatment of Primary Injuries of the Hand" and So-Called Regional Ileitis respectively—Drs Roger Anderson and John A Duncan Seattle, addressed the Cowlitz County Medical Society, Longview, March 17, on 'Fractures of the Upper and Lower Extremities' and "Abdominal Injuries, Diagnosis and Treatment" respectively—Dr John G Cheetham Portland addressed the Grays Harbor County Medical Society, Aberdeen March 3 on Newer Concepts in the Gonorrhea Problem Triphasic Treatment by Use of Local Therapy Sulfanilamide and Hyperpnea Combined—Drs Guy E Griffith and William H Ludwig Tacoma addressed the Pierce County Medical Society, Tacoma March 8 on "Attempts to Correlate Conflicting Ideas of Sinus Surgery and Multiple Sclerosis in Retrobulbar Neuritis" and Submucous Resection of the Nasal Septum respectively

GENERAL

Twenty-Fifth Anniversary of Cancer Society—The American Society for the Control of Cancer celebrated the twenty-fifth anniversary of its founding with a dinner at the Hotel Ambassador March 25. Among the speakers were Drs. James Ewing, New York, Ellis Fischel, St. Louis, and Bowman C. Crowell, Chicago. Clarence C. Little, Sc.D., Bar Harbor, Maine, managing director of the society, presided. Dr. John J. Morton Jr., Rochester, N. Y., was elected president and Dr. George M. Smith, New Haven, Conn., vice president.

Public Health Association Invites Physicians to Portland Meeting—The annual meeting of the Western Branch of the American Public Health Association will be held in Portland, Ore., June 6-8. The secretary, Dr. William P. Shepard, 600 Stockton Street, San Francisco, suggests that physicians attending the annual session of the American Medical Association in San Francisco June 13-17 may wish to attend the public health meeting and remain in Portland for the Rose Festival which immediately follows. Inquiries may be addressed to Dr. Shepard or William Levin, Dr. P. H., 816 Oregon Building, Portland. Dr. Shepard notes that the railroad fare from the East to San Francisco via Portland is the same as to San Francisco direct.

Society News—Two sessions of the sixteenth annual Midwest Safety Conference at the Hotel Sherman, Chicago, May 17-19, will be devoted to consideration of occupational disease. Among the speakers will be Drs. Alice Hamilton, Hadlyme, Conn., health hazards in materials used in painting, Arbie L. Brooks, Detroit, health hazards in the use of solvents in metal cleaning, Milton H. Kronenberg, Chicago, inspection of plants for health hazards, and Clarence O. Sappington, Chicago, who will conduct a "question box luncheon."—Dr. Herbert Fay H. Jones, Little Rock, Ark., was named president elect of the Mid-South Postgraduate Medical Assembly at its annual meeting in Memphis, Tenn., February 15-18. Vice presidents elected were Drs. Lawrence W. Long, Jackson, Miss., Ernest J. Horner, Jonesboro, Ark., and Otis Whitlow, Savannah, Tenn. Dr. Robert M. Adams, Ripley, Miss., is president.

American Neisserian Medical Society—The fourth annual session of the American Neisserian Medical Society will be held in Washington, D. C., May 16-17 at the U. S. Public Health Service building. The first morning will be devoted to a symposium on sulfamidamide, with Dr. Perrin H. Long, Baltimore, as the guest speaker. In the afternoon there will be the presidential address of Dr. Charles C. Norris, Philadelphia and the following section meetings: male clinical, female clinical and research and laboratory. Other speakers will be:

- Dr. Max L. Brodny, Boston: History of Gonorrhea During the Middle Ages.
- Dr. Charles Walter Clarke, New York: Suggestions for Elevating the Standard of Gonorrhea Clinics.
- Dr. Nels A. Nelson, Boston: Providing Treatment for the Indigent.
- Dr. Raymond A. Vonderlehr and Lida J. Usilton, U. S. Public Health Service: The Epidemiology of Gonorrhea.
- Dr. Charles M. Carpenter, Rochester, N. Y.: The Effect of Gonotoxin on Mice and Its Neutralization with Antitoxin.

American Congress on Obstetrics and Gynecology—Plans for an American Congress on Obstetrics and Gynecology in Cleveland during the week of Sept. 11, 1939, have been announced. Dr. Fred L. Adair, Chicago, is general chairman and Dr. James R. McCord, Atlanta, Ga., is secretary of the congress. The directors of the American Committee on Maternal Welfare are the governing body. They are Drs. Leroy A. Calkins, Kansas City, Mo., Robert L. DeNormandie, Boston, George W. Kosmak, New York, Robert D. Mussey, Rochester, Minn., Everett D. Plass, Iowa City, and Philip F. Williams, Philadelphia. The congress is to be organized to meet the interests of various groups, including practicing physicians, medical educators, nurses, public health workers, hospital administrators and others interested. Morning sessions will be reserved for group meetings and the afternoons for general discussions. Evening sessions will be arranged for the public. There will be scientific and commercial exhibits. Inquiries may be addressed to the general chairman at the executive office, 650 Rush Street, Chicago.

Winners in Traffic Safety Contest—Memphis, Tenn., won the national grand prize in the sixth national safety traffic contest sponsored by the National Safety Council for the calendar year 1937. The award was made in recognition of the city's comprehensive safety program as well as its safety record. Memphis had thirty-four traffic deaths as compared to fifty in 1936 and an average of forty-eight for the

three years preceding 1937. The cities that won first places in their population groups were as follows: Milwaukee cities with 500,000 or more, Hartford, Conn., cities of from 100,000 to 250,000, Beaumont, Texas, and Sacramento, Calif., tied among cities of from 50,000 to 100,000. Everett, Wash., 25,000 to 50,000, and Des Plaines, Ill., 10,000 to 25,000. There were 113 cities with populations between 5,000 and 10,000 that went through 1937 without a traffic death. Massachusetts won the grand prize among states because of its low death rate 96 per ten million miles traveled as compared with a national average of 159, its reduction from previous years and its program of safety activities. Bronze plaques were presented to the winning cities and states at a dinner in Washington, D. C., April 12.

Health Among Industrial Policyholders—A new low mortality rate was established in 1937 by the 17,700,000 industrial policyholders of the Metropolitan Life Insurance Company, according to a recent report in the *Statistical Bulletin*. The rate for all causes was 8221 per thousand insured lives the lowest ever recorded by the company. New low records were reported for eight causes: typhoid fever, scarlet fever, tuberculosis, chronic nephritis, diseases arising out of pregnancy and childbirth, homicides, accidental burns and railroad accidents. In this group the tuberculosis mortality continued to drop, contrary to expectations. The 1937 rate was 51.3 per hundred thousand, compared with 54.3 for the previous year. Typhoid for the first time dropped below 1 per cent, with a rate of 0.9. Heart disease was the leading cause of death but the rate was slightly less than that for 1936. 157 is compared with 161, it was found that the rate was declining among young persons. Cancer stood second on the list with a rate of 94.1, compared with 93.9 for the previous year. Diabetes set a new maximum rate of 25 per hundred thousand. The suicide death rate was 8.8, a continued drop since 1932, when the rate was 10.6. The accident rate was the lowest on record for the group of policyholders, 53.6, this was achieved in spite of the increased numbers of wage earners employed and thus exposed to more hazards. Automobile accidents, however, increased by 4 per cent, with a rate of 20.9 as compared with 20.1 in 1936.

Medical Bills in Congress—Bills Introduced—S. 3914, introduced by Senator Barkley, Kentucky, proposes to provide, in addition to the annual sum of \$3,800,000 now available, the following sums for extending and improving maternity care and the care of infants for the fiscal year ending June 30, 1939, \$3,000,000, for the fiscal year ending June 30, 1940, \$8,000,000, for the fiscal year ending June 30, 1941, \$12,000,000, for the fiscal year ending June 30, 1942, \$16,000,000, for the fiscal year ending June 30, 1943, \$20,000,000, and for each fiscal year thereafter, such additional sums as may be needed. H. R. 10442, introduced by Representative O'Day, New York, proposes to amend the Social Security Act by striking from it the exemptions in favor of corporations, community chests, funds or foundations organized and operated exclusively for religious, charitable, scientific, literary or educational purposes, or for the prevention of cruelty to children or animals. H. Res. 473, submitted by Representative Scott, California, proposes to create a House select committee to (1) inquire into the organization, objectives and activities of Group Health Association, Incorporated, of the District of Columbia from the point of view of its effect on medical ethics and the economic soundness and social desirability of this plan of operation and (2) inquire into the activities of the American Medical Association and of state and county medical societies in relation to Group Health Association Incorporated. H. Res. 475, submitted by Representative Shafer, Michigan, proposes to create a House select committee to inquire into the organization and activities of Group Health Association. H. Res. 476, submitted by Representative Shafer, Michigan, provides that whereas Group Health Association organized to provide medical care for government employees obtained from the Home Owners Loan Corporation \$40,000 of the taxpayer's money to defray operating expenses, and whereas this expenditure of \$40,000 by the Home Owners Loan Corporation has been declared illegal and improper by the Comptroller General of the United States, the Appropriations Committee of the House of Representatives and the United States district attorney, and whereas Group Health Association and the Home Owners Loan Corporation have refused to take cognizance of the rulings that this expenditure is illegal and improper. It is resolved that the Attorney General of the United States be instructed immediately to take necessary legal action to recover for the United States Treasury this sum of \$40,000.

The Treatment of Anterior Poliomyelitis

At a meeting of the Manchester Medical Society, Dr R W Brookfield discussed the treatment of anterior poliomyelitis. Apart from its value in diagnosis, he said that lumbar puncture was a useful therapeutic measure, the increased intracranial pressure was diminished and the symptoms were often relieved, particularly with regard to meningeal irritation. There was some experimental justification for giving methenamine, as it had been recovered from the cerebrospinal fluid and had prevented the onset of paralysis in monkeys. Convalescent serum had been extensively used and the serum of many adults who had not suffered from the disease had similar or greater protective power. In the earlier reports the verdict was almost invariably favorable to serum treatment, but controls were lacking. Figures of the epidemics in the United States in 1927-1928 and in Manitoba in 1928 seemed to show a definitely favorable effect, but the figures of W H Park for the New York epidemic of 1931 showed no appreciable influence on the course of the disease. If the virus gained access to the nervous system along the olfactory nerves and then traveled in the nervous system along the axis cylinders, as the work of Hurst and others suggested, it was comprehensible that antibodies introduced into the blood or cerebrospinal fluid had little chance of establishing contact with the virus once infection had taken place. But Brookfield would not take the responsibility of neglecting serum treatment in such a grave disease. Once paralysis had supervened, the problem of treatment became increasingly orthopedic. The accepted treatment was rest of the limb by means of light splints and prevention of stretching of the paralyzed muscles.

The Promotion of Physical Development

In opening a discussion at a meeting of the section of physical medicine of the Royal Society of Medicine, Lord Dawson, president of the Royal College of Physicians, said that proficiency in games often existed with deficiency of frame and function. Also games, unless correlated with basic physical training, could inflict overstrain. Sports and games were the fulfilment of physical training and should rest on it, for planned physical exercises increased the strength, control and response of the body. Moreover, physical training developed certain qualities which were basic to sound physical education—posture, poise, flexibility and rhythm of movement and efficient respiration. The government had decided to establish a national school of educative and recreative training, and the board of education is actively concerning itself with the realization of that project. In it teachers of anatomy and physiology will work side by side with teachers of physical training. The total functional value of the individual will be studied, having regard to his makeup and environment.

Physical education would need the guidance of trained physicians. In the future those who aspired to be medical officers of schools would require to include in their training a knowledge of physical education. Other measures recommended by Lord Dawson were to push to the forefront the best of our youth who would create a standard for their own generation, to consider the granting of loans (as in Germany) to medically approved marriages, the obligation to repay being reduced on the birth of each child, and to institute motherhood clinics. In short we should plan for quality. When posts were to be filled by competitive examination, this should include tests not only for mind but also for body.

A Sealed Faraday Document Opened After a Hundred Years

In 1832 Michael Faraday deposited a sealed letter with the Royal Society, which has just been opened. At the time he wrote the letter only the most elementary facts were known about magnetism and electricity. Electric bells and telegraphs were unknown and it had been discovered only a few years previously that magnetism could be produced by electricity. Faraday argued that conversely it should be possible to produce electricity from magnetism. For nearly seven years his experiments were unsuccessful until in 1831 the reason of his failures became apparent. Then in a few days he made a series of brilliant researches from which the whole science of electricity and magnetism developed. He found that an electric current was generated whenever a conductor was moved toward or away from a magnet. He was led to conclude that "magnetic action is progressive and requires time for its transmission." This was a revolutionary theory—the instinctive deduction of a brilliant experimentalist—which he could not prove. But he was so sure of its truth that he took the unusual course of depositing a sealed statement of his views with the secretary of the Royal Society, in whose safe it has since remained. In it he wrote "I am inclined to compare the diffusion of magnetic forces to the vibrations on the surface of disturbed water or those of air in the phenomena of sound."

These views I wish to work out experimentally, but as the experiments may in their course be subject to the observation of others, I wish, by depositing this paper in the care of the Royal Society, to take possession, as it were, of a certain date, and so have right, if they are confirmed by experiments, to claim credit for the views at that date." Maxwell proved mathematically in 1865 that electromagnetic phenomena are propagated through space in the form of a wave motion with the velocity of light, but it has not been previously known that Faraday was the original author of the theory in 1832. The theory remained unconfirmed experimentally until Hertz showed in 1888 how to produce and detect electromagnetic waves. It is universally recognized that Faraday was the greatest experimentalist that the science of electricity has known, but here is a new proof of his genius. His unerring instinct in concerning the time factor and the wave theory, which he had no means of proving, is amazing.

Early Diagnosis of Gastric Cancer

An effort is being made at the clinic of Prof A Gosset of Paris to recognize cancer of the stomach at the onset. A team has been organized which includes, besides the surgeon, a radiologist, an internist and a pathologist who have intensively studied the question of the earliest stages of gastric cancer for years. At the March 11 meeting of the Societe medicale des hopitaux a case of incipient gastric cancer was reported by Professor Gosset and his co-workers Drs Guttman, Bertrand and Garcia-Calderon. This case forms one of a series reported during the last eighteen months. Although invisible on gross examination at operation, the diagnosis of gastric cancer could be readily made microscopically. A woman aged 58 had noticed digestive disturbances during the preceding six or seven months, becoming very marked during the four months before being first seen by Professor Gosset in October 1937. Radiography revealed in the prepyloric region of the stomach a change in the outline which Dr Rene Guttman has termed *niche en plateau*, which can be translated as a shallow niche. It was about 1 cm long and sharply outlined. Although a diagnosis of malignancy was made on the basis of the radiographic examination, the patient was

given the benefit of medical treatment for a period of three weeks in order to exclude a cancer, because a consultant had been skeptical with regard to the diagnosis of malignancy. The films following this period of medical treatment failed to show any changes in the region of the niche. At operation the stomach and duodenum were inspected and palpated but nothing abnormal was found. A gastrectomy was performed by Professor Gosset. On gross examination of the entire lesser curvature of the specimen, neither an ulceration nor an induration could be detected. Microscopic study, however, by Dr. Ivan Bertrand of serial sections from 6 to 8 cm long of the entire pyloric and prepyloric region disclosed a diffuse gastritis of an atrophic and in places of an erosive type. In one of the sections close to the lesser curvature a slightly depressed area 1 cm in length was found which presented the changes characteristic of malignancy. A detailed description of these changes was submitted with the report.

Association of Pulmonary Abscess and Tuberculosis

Prof. F. Bezançon and his associates at the March 8 meeting of the Académie de médecine reported thirteen recent cases of active tuberculosis in patients suffering from pulmonary abscess formation. The object of the authors was to direct attention to cases in which the positive result of the routine search for tubercle bacilli by the smear, culture and animal inoculation methods is the only evidence of the association of the two pathologic conditions as compared to severe forms of pulmonary tuberculosis in which the occurrence of abscess formation due to nontuberculous organisms is a coincidence. The tuberculosis may develop at the site of the abscess at the time of formation of the latter or it may appear relatively late following prolonged suppuration and be present at some distance from the abscess on the same or opposite side of the body. The routine use of radiography in different positions reveals latent tuberculous lesions which are not to be found in the ordinary dorsal and frontal views. Tubercle bacilli are to be found in abscess of the lung even when gross and microscopic evidence of tuberculosis is not present. An associated tuberculosis is most frequently found either during the acute stage of a pulmonary abscess or close to the scar which represents a healed suppurative focus. When tuberculosis develops at a late period of abscess formation the question arises whether the lung, modified by the sclerotic changes incident to the healing of the abscess, had not lost its power of resistance and thus favored localization of the tubercle bacillus. The authors pointed out that it is important clinically to distinguish the two types of tuberculosis in cases of pulmonary abscess. The mere presence of tubercle bacilli in cases of the pulmonary abscess does not serve as a contraindication to operative intervention, whereas active tuberculosis associated with a pulmonary abscess is a contraindication to operation.

Medical Examination of Chauffeurs

Reference was made in previous letters to the report of a commission appointed by the Académie de médecine of Paris on the extension of the obligatory medical examination to all drivers of passenger cars. An existing law already covers chauffeurs of motor trucks, busses and electrically driven locomotives. The discussion of Professors Claude and Guillaum was cited in the Paris letter of February 12 (*THE JOURNAL*, March 12, p. 825). At the March 8 meeting additional points were brought out during a continuation of the discussion. Dr. Fredet said that one cannot deny that certain physical and mental defects of chauffeurs constitute a danger for the public. However, to insist on a complete obligatory medical examination for every one who is to be granted a driving license would give rise to far more work than can be estimated at first glance. This had already been pointed out by Professor Claude. The number of accidents due to road conditions and

mechanical defects are decreasing every year whereas the opposite is true of the human factor. The majority of accidents at the present time are the result of neglect to comply with the regulations as to speed, careful approach to street and railroad crossings and disregard of traffic lights. A compulsory medical examination would be of aid only in decreasing the number of accidents due to the last named factor, which in many cases is the result of color blindness. According to statistics, at least 5 per cent of all males suffer from color blindness. This gives one an idea of the number of chauffeurs who cannot distinguish the color of signal lights, especially toward evening or during a fog in a large city. To reduce accidents due to color blindness to a minimum the speaker suggested that a single color be employed to indicate Go and two colors to indicate Stop. The color blind chauffeur would then know, when he saw two colors, no matter which, that this indicated Stop.

Another criticism of the present signal system in Paris which exists also in many other large cities, is that the yellow light which flashes between the red and the green is of such short duration that many pedestrians are caught on the street because they began to cross during a stop signal for automobiles but were unable to reach the other curb before the go light again functioned. In some cities a special light is used to indicate the interval during which pedestrians can cross a street.

In continuing the discussion Dr. Strohl said that accidents occurred even though a strict medical examination had been made. He cited the case of a locomotive engineer who had undergone such an examination before being employed in that capacity. Following his acceptance he had several attacks of epilepsy from which he had apparently never suffered before. Of 26,654 accidents from 1930 to 1932 inclusive in ten departments (counties), only seventy-five were the result of a mental or physical defect.

At the conclusion of the discussion, the report of the committee to recommend obligatory examination of all drivers of passenger cars was unanimously adopted.

March 14, 1938

Earlier Puberty of German Youth

In recent years numerous references to an acceleration in the puberal development of both sexes have appeared in the literature of various countries. Medical examinations in the German army have likewise disclosed a tendency toward more rapid growth. For example at about the turn of the century about 15 per cent of the men were less than 160 cm in height whereas in the year 1935 only 7.5 per cent of the men were below this height. Similarly, around 1900 the height of 16 per cent of the men exceeded 180 cm and in 1935 54 per cent were above this height. Corresponding shifts have also taken place at the intermediate levels of height. Some German authors have adduced evidence which indicates that among the youth there has been a general increase not only in height and weight but in general bodily development as well. For example an increasingly large percentage of children are able to walk before the end of the first year in marked contrast with former times. Dentition both primary and secondary also appears to begin earlier in life. Moreover the time at which boys' voices break has been advanced from one to two years. In Westphalia the onset of puberty was observed in the year 1933 to occur about one and a half years earlier than in 1914. According to investigations made in the year 1913 50 per cent of girls began to menstruate between the fourteenth and sixteenth years, only 13 per cent between the eleventh and the thirteenth years and 27 per cent between the seventeenth and nineteenth years.

The most recent group survey of pubescence was made by Dr Hans Oster, senior municipal medical counselor of Nuremberg, who reports his observations in the *Öffentlicher Gesundheitsdienst*. Oster's material consisted of 15,000 children. Of 8,000 girls 12.3 per cent had menstruated before they were 12 years of age, 32.2 per cent before the age of 13, 59.1 per cent before the age of 14. All the Nuremberg girls had begun to menstruate before reaching the age of 17. It may therefore be said that by and large girls mature on an average from one to one and one-half years earlier than they did in the last years of the prewar period. Among the 6,000 boys studied, breaking of the voice, appearance of other secondary sex characteristics and certain behavior traits were evaluated as signs of puberty. As among the girls, there was a tendency toward earlier prepubescence. On the basis of older data the average time of onset of puberty in boys had been placed between the fourteenth and sixteenth years. Oster found that the earliest established pubescence in the boys of his material occurred between the ages of 11 and 12, more than one third of the boys had become pubescent before they had reached the age of 13, nearly three fourths before the age of 14 and more than four fifths before the age of 15. So it may be said that the onset of male puberty has been advanced about one and one-half years. As to whether this earlier maturation of the youth should be regarded as a favorable or unfavorable phenomenon, the present state of knowledge does not permit a conclusion.

Alcohol and Safe Driving

Professor Sachsenberg has conducted a series of new blood tests at Dresden which bear on the problem of alcohol and safe driving. A summary of his observations follows. In Germany an alcohol value of 1.5 per thousand in the blood is generally considered proof that the person is under no circumstances in condition to drive. But in Norway, for example, the corresponding alcohol content is fixed at 0.5 per thousand. At the Psychotechnic Institute of the College of Technology, Dresden, the author, in collaboration with engineers, psychologists and physicians, attempted to determine how great an alcohol content of the blood would produce physical impairment incompatible with the safe direction of a motor vehicle. Such an impairment was assumed if the driver in question while under the influence of alcohol was observed to drive more recklessly than 90 per cent of all normal drivers. A large group of automobile drivers and nondrivers as well volunteered for participation in the driving tests and blood examinations. In the accompanying table are set forth the percentages of persons judged incapable of driving safely after partaking of alcohol, and the corresponding alcohol values of the blood which rendered them unfit.

| Alcohol Content of Blood Per 1 000 | Drivers Incapacitated Per Cent |
|---------------------------------------|--|
| 0.2 | 20 |
| 0.4 | 40 |
| 0.5 | 49 |
| | (About 2½ small bottles of beer) |
| 0.6 | 58 |
| 0.7 | 66 |
| 0.8 | 75 |
| 0.9 | 80.5 |
| 1.0 | 87.5 |
| 1.1 | 90 |
| 1.2 | 93 |
| 1.3 | 96 |
| 1.4 and over | 100 |
| | (About 2 bottles of moderately heavy Rhine wine) |

According to these data, one half of all drivers are incapable of safe driving after imbibing from two to three small bottles of beer. And after finishing two bottles of moderately heavy Rhine wine scarcely any one can be responsible for the guidance of a motor vehicle. There are exceptions, of course, especially at the level of a 1 per thousand alcohol content in

the blood, but these can be carefully verified by psychotechnic examination methods. Broadly speaking, one can conclude on the basis of these experiments that drivers should be warned against ingestion of even trifling amounts of alcohol before beginning a trip.

Prof Max Neisser Is Dead

Prof Dr Max Neisser, for many years professor of hygiene and bacteriology at Frankfurt on the Main, died there, aged 69. He was particularly well known for his bacteriologic work on the differential diagnosis of the diphtheria bacillus and on staphylococci. The phenomenon of deviation of the complement (Neisser-Wechsberg phenomenon) bears his name, as does a complement binding reaction for biologic differentiation of proteins (Neisser-Sachs method). He also made valuable contributions to knowledge of the mutation of bacilli.

March 15, 1938

Uniform Medical Fees

The head of the government has issued a decree which establishes a nationally uniform scale of medical honorariums. The amounts stipulated represent the minimal fees deemed compatible with professional dignity and no practitioner may ask less for his services unless his client is the father of a family who has five or more dependent children and who accordingly, is entitled to a 20 per cent reduction. The scale for professional visits to a patient's residence are as follows: first call, 20 lire, successive calls, 15 lire each, emergency call, day 25 lire, night 40 lire, consultation at patient's home, 30 lire for the attending physician, 60 lire for the consultant. Corresponding rates are fixed for surgical, obstetric and gynecologic services. Another decree soon to be issued will regulate the honorariums of specializing physicians.

Nomenclature of Medical Institutions and Offices

The minister of the interior has issued regulations to end the commercial exploitation (in advertising and so on) of medical institutions, offices and the like. The new law stipulates that the terms "clínica" and "políclínico" may be applied only to institutions connected with the university medical schools, private institutions of a medical nature should be styled "case di cura" (nursing homes) or "case di salute" (sanatoriums). The term "istituto" can now be applied only to a center of many coordinated activities the aim of which is predominantly scientific, cultural or educational, it must not be applied to case di cura or to mere medical offices. The term "studio" (laboratory) must be applied only to premises dedicated to clinical research studies and implies the presence of proper equipment for laboratory examination. The term "gabinetto" (office), since it implies merely premises equipped for ordinary clinical examination and treatment of patients, may be applied to the office of a general practitioner. The term "poliambulanza" (general or municipal outpatient infirmary) must be restricted to premises given over to more specialized procedures.

The Bulgarian Therapy of Parkinsonism

Professor Gandellini of Pavia recently reported to the medical society on the use of Bulgarian therapy in encephalic parkinsonism. The author studied the Buscaino reactions of 104 persons. In the more severe forms, those characterized by hyperemia and hypertonia, the precipitate was usually grayish. Other reactions in order of frequency were brown and black. In half of the moderately severe cases the precipitate was gray. After the Bulgarian therapy was begun not only were the neurologic symptoms improved but modifications were observed in the Buscaino reaction as well, cases in which dark precipitates had been elicited at previous tests tended to give lighter or clear reactions.

The author also studied the blood pictures in ninety cases of parkinsonism which later underwent Bulgarian treatment. Tests of capillary blood, venous blood and medulla osseum were the three criteria applied. In the capillary blood prior to treatment, certain phenomena were observed: general abnormal increase in globular values, an almost normal proportion of leukocytes and blood plates, a slight reticulosis, plain deviation of Arneth's formula frequently in combination with neutrophilia and lymphopenia, discrete eosinophilia. Some time after the beginning of treatment (the maximal period of observation was three years) the author noted that the globular values tended to become stationary and the white globules tended to diminish, there was also a reduction in the number of neutrophils and monocytes, and an increase in lymphocytes and eosinophils. The author considers that the hematologic characteristics of encephalic parkinsonism justify the supposition of an automatic, humoral regulation of the blood count. The Bulgarian therapy produces clinical amelioration of the neurologic symptoms and also brings with it favorable changes in the blood picture.

Congress of Obstetricians and Gynecologists

The Societa Italiana di ostetricia e ginecologia held its thirty-fourth national convention in Rome. Professor Artom of Sant'Agnes clinic was chairman of the executive committee. Professor Jayle represented the Societe française de gynecologie and Professor Stamatev of the obstetric clinic, Sofia, represented the gynecologists of Bulgaria.

Professor Garfani, director of the Clinica di Roma, called attention to the need for a better coordination of extant maternal and infant welfare agencies. A hygienic program should be worked out that would assure adequate supervision and timely care of the mother during pregnancy, parturition and the puerperium, as well as care of the newborn infant. Such a program would go far to reduce morbidity and mortality of both mothers and babies. It cannot be realized, however, until the medical schools and the hospitals furnish better training in obstetrics and gynecology. The author advocates the establishment of special residence units for prospective obstetricians, the training of the students should be better coordinated with that of the resident students at the pediatric clinics. Compulsory insurance of the gravid woman should be extended throughout the population and eventually become totalitarian. Likewise a closer collaboration is to be encouraged between gynecologists and pediatricians in the study of diseases of the prepuberal female genitalia as the present lack of understanding of these disorders often conduces to impaired health of the adult woman.

The first formal report was submitted by Professor Cova of Turin, his subject was nutrition of the pregnant woman. Methodical studies of the increase in body weight of pregnant women at the Turin clinic demonstrated that in the late months of gestation primigravidae experience a mean gain of 50 Gm per diem plurigravidae a mean gain of 70 Gm per diem. Basal metabolism is always at least 20 per cent and sometimes as much as 50 per cent above normal. It is estimated that an expectant mother will require a daily intake of 3000 calories. Any study of the qualitative physiologic equilibrium must take into account above all the presence in the nutriment of essential amino acids, vitamins, phosphates and calcium. These salts are needed for the development of the fetal skeleton. Vitamin A deficiency easily leads to abortion or premature parturition. Lack of vitamins of the B group inhibits intra-uterine fetation. Vitamin C the antiscorbutic controls the metabolism of the osseous skeleton and preservation of the teeth and besides stimulates the production of blood platelets. It acts indirectly on the coagulative powers of the blood and this may be of utmost importance during the postpartum period. Vitamin D the antirachitic vitamin is of importance because of its value in calcification. Vitamin E the antisterility vitamin exerts an influence on the continuation of pregnancy.

In the discussion of Cova's paper, Professor Fori, Milan physiologist, said that in general the evaluation of the proper requisites of the gravida may be exaggerated. He estimated that about 20 Gm was sufficient for a normal gravida.

Courses in Puericulture

The minister of public instruction has decreed that all girls pupils in secondary schools shall be offered courses in the care of infants and in puericulture. This program is a pendant to the present compulsory military training of boys of secondary school age. The purpose of the new courses will be to familiarize girls with (1) the duties of the woman in the upbringing of the family and in the prevention of sickness (since the health of a people depends on how well these duties are performed), (2) hygiene as the source of individual and national health and (3) hygiene of the nursing and training of the child. The courses will be conducted by professors or the staffs of various centers for maternal and child welfare. In addition to the classroom lessons, opportunity will be offered for practical training.

Alessandro Lustig Is Dead

Senator Alessandro Lustig, professor emeritus of general pathology in the University of Florence, died unexpectedly at Marina di Pietrasanta. Lustig held doctoral degrees from both Vienna and Turin and he was a pupil of Brücke and of Bizzozzero. While quite young, he won a competitive examination for the chair of general pathology at Cagliari. From there he was called to Florence, where he taught for more than forty years and founded a school that has given more than twenty eminent men to the scientific institutions of Italy. A volunteer in the World War, he saw front line service as colonel in the medical corps. It was Lustig who organized the antigas defense in the Italian army. Following his retirement from teaching he continued to head a center at Florence for research on defense against chemical warfare.

Lustig's scientific activity was prodigious. Of far reaching importance were his morphologic-bacteriologic investigations of cholerigenous *Vibrio* and of anticholera and antityphoid inoculation. In collaboration with Galleotti he demonstrated the presence of Flemming's intermediary body in carcinoma cells. In the field of bubonic plague research he demonstrated by experiments with human and animal subjects that the nucleoprotein of *Pasteurella pestis* is an excellent vaccinal medium. As chairman of a ministerial commission for the study of pellagra, Lustig worked out a program of school hygiene and prophylaxis of this disease, which at that time was endemic in certain regions of Italy. Lustig went to India at the invitation of the British government on the occasion of an epidemic of bubonic plague there. He also fulfilled similar missions to Brazil and Argentina, where he studied malaria, leprosy and undulant fever.

Lustig was for many years editor of the scientific journal *Lo sperimentale* which came to be devoted to the literature of biology and which gained world wide recognition as an *Archiv di biologia normale e patologica*.

Marriages

WILLIAM EMMETT DENMAN JR. Greenwood Miss to Miss Sal Whitaker of Greenville in February.

ISAAC HAYNE Congaree S. C. to Miss Sue Stevenson of Columbia in Denmark February 8.

ROY O. HAWTHORNE to Miss Louise P. Bidwell both of Kankakee Ill. in February.

HARRY H. JENKINS to Miss Marina Mayo both of Knoxville Tenn. February 19.

BLANCHE HOPNER MILDOD to Mr. A. L. Bach both of Pico Calif. recently.

Deaths

Claude Granville Crane, Brooklyn, Columbia University College of Physicians and Surgeons, New York, 1900, member of the Medical Society of the State of New York, and American Laryngological, Rhinological and Otological Society, in addition to serving on various committees he was secretary of the Medical Society of the County of Kings, 1911-1913, fellow of the American College of Surgeons, on the staff of the Brooklyn Hospital and the Brooklyn Eye and Ear Hospital, aged 61, died, February 27

James Robert Dykes Ⓢ Surg, Lieut Commander, U S Navy, retired, Marshallville, Ga, University of Virginia Department of Medicine, Charlottesville, 1897, entered the navy in 1903 and retired in 1915 for incapacity resulting from an incident of the service, formerly health officer of Grady County and Thomas County, aged 64, died, February 20, of heart disease

William W York, Ashdown, Ark, Memphis (Tenn) Hospital Medical College, 1901, member of the Arkansas Medical Society, past president of the Little River County Medical Society and the State Medical Board of the Arkansas Medical Society, aged 61, died, February 3 in a hospital at Texarkana of injuries received in an automobile accident

Harold Bertram Hedrick Ⓢ Kansas City, Mo, University Medical College of Kansas City, 1913, member of the American Academy of Ophthalmology and Oto-Laryngology served during the World War, aged 47, on the staffs of the Trinity Lutheran, Kansas City General, St Luke's and Mercy hospitals and St Mary's Hospital, where he died, February 21, of cerebral hemorrhage

John Pierce De Witt Ⓢ Canton, Ohio, Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1895, member of the House of Delegates of the American Medical Association since 1923 fellow of the American College of Surgeons, on the staff of the Aultman Hospital, aged 67, died, March 29, of cerebral hemorrhage

Ezra T Goble Ⓢ Earlville, Ill, Rush Medical College, Chicago, 1874, an Affiliate Fellow of the American Medical Association, past president of the La Salle County Medical Society, for many years member and president of the school board, formerly mayor of Earlville and bank president, aged 87, died, February 23, of chronic myocarditis

William Alfred Buice, Chelsea, Okla, University of Oklahoma School of Medicine, Oklahoma City 1930, formerly director of laboratories at the Eastern State Hospital Medical Lake, Wash, past president of the Washington State Public Health Association, aged 47, died, February 3, in Santa Monica, Calif, of coronary thrombosis

William Allen Prouty, Burlington, Wis, Rush Medical College, Chicago, 1893 member of the State Medical Society of Wisconsin, served during the World War, for many years county physician, at one time city health officer of Burlington formerly on the staff of the Memorial Hospital, aged 75, died, February 5, of pylonephritis

William Hazen Freeman, Ashland, N Y, Chicago Homeopathic Medical College 1900, member of the Medical Society of the State of New York formerly associate professor of materia medica at the New York Homeopathic Medical College and Flower Hospital, New York, aged 67, died, February 27, of coronary thrombosis

Dottery Holden Ward, Bay St Louis Miss, University of Tennessee College of Medicine Memphis 1914 member of the Mississippi State Medical Association aged 55, died February 5, in a hospital at Gulfport of burns received when a gasoline heater in his office exploded

Joseph Eugenberger, Worcester, Mass, Long Island College Hospital Brooklyn, 1932, member of the Massachusetts Medical Society served during the World War, aged 44 on the staff of the Worcester City Hospital, where he died February 28 of lobar pneumonia

Harry E Wilkins, Petersburg Ill, College of Physicians and Surgeons Keokuk, Iowa, 1893, member of the Illinois State Medical Society, formerly mayor, county coroner and member of the local board of education, aged 72, died February 22 of myocarditis

Abram Miller Ⓢ Kansas City, Mo, Washington University School of Medicine St Louis 1895, at one time professor of materia medica University Medical College of Kansas City on the staff of St Joseph Hospital, aged 63, died February 12 of coronary occlusion

J W Kenward Shaw, New Iberia, La, College of Physicians and Surgeons, Baltimore, 1887, member of the Louisiana State Medical Society, formerly parish coroner and member of the school board, aged 73, died, February 13 of angina pectoris

Pringle George Tait Ⓢ Toledo, Ohio, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1900, served during the World War aged 62, on the staff of St Vincent's Hospital, where he died, February 16, of bronchiectasis

Archibald John Valteau, Morrisville, Vt, Queen's University Faculty of Medicine, Kingston Ont, Canada, 1891, member of the Vermont State Medical Society, aged 71, on the staff of the Copley Hospital where he died, February 18

Jefferson Gillum Smith, McDonough, Ga, Atlanta College of Physicians and Surgeons, 1899, member of the Medical Association of Georgia, past president of the Henry County Medical Society, aged 61, died February 5, of cancer of the bone

Frank J Spilman Ⓢ Connersville, Ind, Medical College of Ohio, Cincinnati, 1897, past president of the Fayette-Franklin County Medical Society, aged 65, died, February 7, in a hospital at St Petersburg, Fla, of intestinal hemorrhage

Harry Stearns Platts, Troy, N H, Dartmouth Medical School, Hanover, 1898, member of the New Hampshire Medical Society, served during the World War, aged 61, died suddenly, January 7, of coronary thrombosis

Nicholas J Nye, McHenry, Ill, Memphis (Tenn) Hospital Medical College 1899 member of the Illinois State Medical Society, aged 66 died, February 16, in Miami, Fla, of coronary occlusion and arteriosclerosis

Harry Raymond Thomas, Dallas, Texas, Tulane University of Louisiana Medical Department, New Orleans 1900, formerly member of the city board of health, aged 59, died in February of coronary thrombosis

Albert G Meyer, San Francisco, University of California Medical Department, San Francisco, 1890 aged 68, died, January 1, in the San Francisco Hospital of diverticulitis of the sigmoid and pylephlebitis

Casimir Francis Pawlicki, San Francisco, University of California Medical Department, San Francisco, 1894, aged 65, died January 4, in the French Hospital of chronic myocarditis and arteriosclerosis

B R Bradford, Linden Ala, Medical College of Alabama, Mobile 1904, member of the Medical Association of the State of Alabama, aged 55, died, February 21, of bronchopneumonia

Frank Coleman, Hamilton, Ont, Canada, University of Toronto Faculty of Medicine, Toronto, Ont, 1894 aged 70, died, February 8 in the Hamilton General Hospital

William Benjamin Brooks, Mohawk, N Y, University and Bellevue Hospital Medical College, New York, 1901, aged 62 died, February 3, of cerebral hemorrhage

Horace A Reddish, St Louis, St Louis College of Physicians and Surgeons 1908, aged 51, died, February 5, in New Orleans of hypertensive heart disease

Dominique Francis Gaspard, Montreal, Que, Canada, Laval University Medical Faculty, Montreal, 1918, aged 53, died February 6 in a local hospital

Samuel R Turner, Michigan Center Mich, University of Louisville (Ky) Medical Department 1888, aged 79, died, February 7, of cerebral hemorrhage

Ethan St Clair Milford, Hayward, Calif, Hering Medical College Chicago, 1901, aged 66, died, January 19, of myocarditis and cerebral thrombosis

Manly L Taylor, Columbus, Ga, Leonard Medical School, Raleigh N C 1906, aged 56 died, February 6, of cardiac insufficiency and nephritis

John Arthur Jones, Springfield, Ohio, Jefferson Medical College of Philadelphia, 1890, aged 75, died, January 31, in Dayton of myocarditis

Louis G E Boucher, St Valerien Que, Canada, Victoria University Medical Department, Coburg Ont 1879 aged 85 died February 4

Calvin Eugene Camp, San Pablo Calif, Cooper Medical College San Francisco, 1885, aged 71, died, January 3, of pneumonia

Walter S Terhune, Brooklyn New York Homeopathic Medical College, 1877, aged 84, died, February 10, of myocarditis

Harry Ballou Bryson, Los Angeles, Cleveland Medical College 1893 aged 76 died January 30 of myocarditis

Annie Wightman Hunt, Providence R I, College of Physicians and Surgeons Boston, 1884 died January 23

STATEMENT ABOUT INFANTILE PARALYSIS

To the Editor—There is at present no generally accepted preventive of poliomyelitis, nor any effective remedy in the acute stage, other than absolute rest. Complete rest is so important in the early days of this inflammation of the central nervous system that it is usually far better to leave the child in bed at home when the disease is first suspected than to move him any appreciable distance to a hospital, particularly if the move is a fatiguing one.

The early manifestations on which the disease can be suspected are fever, headache, irritability, possibly vomiting, perhaps a tremor in the hands which may cause the patient to spill his glass of water, and in particular a tender rigid spine, which will make it impossible for the child to touch his chin to his knee.

When any considerable proportion of these manifestations are present, a doctor should be called to examine the patient and to draw off and examine some of the spinal fluid to confirm the diagnosis and perhaps relieve the headache, but otherwise the child should be disturbed and moved literally as little as possible. When this is done, three out of four children in whom the disease has progressed to this degree will nevertheless escape the paralysis entirely.¹

Should a patient acquire any paralysis, particularly involving an extremity, a competent orthopedic doctor should be consulted at once, so that the affected part can be immobilized properly at the earliest moment. For even as early rest of the entire child helps to prevent paralysis, so early rest of a weakened muscle helps to prevent permanent crippling.

This statement has been endorsed by Josephine B. Neal, Sidney David Kramer, William H. Park, Thomas Parran, James P. Leake and the Medical Board of the Willard Parker Hospital.

PHILIP M. STIMSON, M.D., New York

NOMENCLATURE OF THE VITAMIN B COMPLEX

To the Editor—With gratitude one reads the comprehensive and authoritative article by Dr. Nelson (The Components of the Vitamin B Complex, *THE JOURNAL*, February 26, p. 645), but because the article is authoritative it is doubly unfortunate that it should contain two inaccuracies logically followed by a definition of one of the components at variance with the definition as it occurs in the literature. There has been so much confusion in the nomenclature of this group and the group contains so many members that it is absolutely essential to fix one term and only one on each entity wherever possible if we are to avoid further confusion and to benefit from Dr. Nelson's authority.

In his paragraph on the filtrate factor he says: "In attempts to fractionate the whole vitamin B complex it has been found that if vitamin B₁ and riboflavin are first removed, further fractionation can be accomplished with fuller's earth. The fraction remaining after such adsorption is free from B₁ and has been designated the filtrate factor. This is not correct, as the only definition of the filtrate factor to be found in the literature is that laid down by Lepkovsky and Jukes (*J. Biol. Chem.* 114:109 [May] 1936), which has not been modified by any other workers who have adopted it. It is given in the title of their paper and reads: the filtrate factor (a water-soluble

vitamin belonging to the vitamin B complex and preventing a dietary dermatitis in chicks)." This definition is precise, supplying a name for what is believed to be a single chemical substance.

The second inaccurate statement is that "evidence is accumulating which indicates that a nutritional dermatosis in chicks may be closely related to human pellagra." Suggestive evidence that the two diseases are caused by lack of different factors from the diet was found by Jukes (*J. Biol. Chem.* 117:11 [Jan] 1937) and more recently decisive evidence has appeared (Dann, *W. J. Science* 86:616 [Dec 31] 1937; Dann, W. J., and Subba Row, Yellapragada, *J. Nutrition* to be published) showing that the filtrate factor and the P-P factor are separate chemical entities; the chick dermatosis is not therefore closely related to human pellagra.

Following these two inaccurate statements, Dr. Nelson has logically stated in his definition that the filtrate factor "contains chick dermatosis, blacktongue and P-P factors." Thus he is now extending the definition of the filtrate factor to cover a second factor in addition to that described in the definition herebefore universally accepted by writers on this subject.

W. J. DANN, PH.D., Durham, N. C.

PRESENT STATUS OF NICOTINIC ACID IN THE TREATMENT OF PELLAGRA

To the Editor—The enthusiastic reception of the report by Elvehjem and his associates on the efficacy of nicotinic acid and its compounds in curing blacktongue and its immediate application to the problem of human pellagra are natural and commendable, but there is reason to believe that this discovery may be exploited before adequate knowledge of essential facts is available.

It would seem justifiable to call attention to paragraphs 7 and 8 of the summary and conclusions of the paper by Spies, Cooper and Blankenhorn published in *THE JOURNAL* February 26. They emphasize that dosage is yet uncertain and that, while nicotinic acid is potent against the mucous membrane lesions of pellagra, further study is necessary before it can be considered a specific for the whole pellagra syndrome.

Clinical experience in widely separate localities indicates that nicotinic acid causes rapid, even spectacular, improvement and remission in pellagrins in the presence of severe dietary inadequacy. Dosage has varied much and oral and parenteral administration have been effective. Treatment periods have been as short as three days and as long as four months. In general the results have been comparable with those produced by large doses of liver extract except that cutaneous lesions have healed more slowly. The effects on nervous manifestations of the disease are still uncertain.

The permanence of cure produced by nicotinic acid will doubtless depend on the ability of patients to secure an adequate diet or a constant ration of the drug to supplement inadequate diet. Even so it is questionable whether any one supplementary dietary factor will maintain health indefinitely. Spies, Cooper and Blankenhorn observed a relapse after apparent cure (case 6) and I have seen a fulminating febrile relapse two weeks after complete remission secured with nicotinic acid. In both instances the diet was seriously inadequate.

While present evidence is strongly in favor of the assumption that nicotinic acid is the P-P factor of Goldberg, the total number of patients treated is small, probably not exceeding fifty, and the time since treatment was started is short. It is most desirable that minimum effective dosage for cure, maintenance and prevention be determined by the controlled observations of experienced investigators and that the indiscriminate use of nicotinic acid be strongly discouraged until this information is available.

V. P. SIDENSTICKE, M.D., Augusta, Ga.

¹ This proportion varies in different epidemics. In the large epidemic of 1931 approximately 82 per cent of the patients admitted to the Willard Parker Hospital in the preparalytic stage or five out of six escaped the paralysis. In other and smaller epidemics the figures have been as low as two out of three.

CORONARY AND CEREBRAL EMBOLISM AND THROMBOSIS

To the Editor—How can a blood clot in a plantar vein travel up and plug a coronary artery or a cerebral artery? The foramen ovale was closed. Has this ever been done experimentally on animals? If so please cite. Just how does this clot pass the pulmonary network? Is a coronary thrombus or embolus the same and caused the same way?

M D Maryland

ANSWER—It is impossible for a blood clot in a systemic vein to plug a coronary artery or a cerebral artery unless there is a septal defect in the heart. If there is a septal defect and a systemic venous thrombus passes through it, the condition is called paradoxical embolism.

Coronary embolism is rare, in contrast to cerebral embolism. Coronary occlusion occurs in the great majority of cases either gradually without the production of infarction or suddenly by thrombosis (only very rarely by embolism) with the production as a rule of myocardial infarction. The thrombus is laid down in situ in the coronary artery, almost always in a very narrow lumen and superimposed on extensive atherosclerotic change in the wall of the artery. The exact mechanism of the production of coronary thrombosis is, however, still a mystery.

TREATMENT OF PREEPITHELIOMATOUS KERATOSES WITH ROENTGEN RAY

To the Editor—What is the technic and dosage for treating the preepitheliomatous keratoses with x-rays in terms of milliamperes and time as I do not have a roentgenometer? Is this method as satisfactory as radium treatment?

M D Kansas

ANSWER—Treatment of preepitheliomatous keratoses can be carried out as successfully with roentgen rays as with radium and in much less time.

The indirect measurement of the dosage is based on four factors—milliamperes, voltage, distance from the target and time. The term skin unit is understood to be the amount of irradiation necessary to produce erythema or epilation. Thus the dosage has been usually given, until rather recently, in terms of skin units. Years ago MacKee determined the factors involved and demonstrated how the factors could be varied to obtain the erythema dose. The following factors were the basis for computation of the dosage: 2 milliamperes, a spark gap of 6 inches or its equivalent in voltage, a distance of 8 inches from the target and an exposure of three minutes. The dosage for the keratoses depends on the thickness of lesion and whether or not it has become an epithelioma. If the lesion is thick, maceration with diluted solution of sodium hypochlorite and removal of the keratosis would permit of examination of its base to determine whether malignancy has developed. Unless one has had experience in the diagnosis and treatment of such lesions undertreatment rather than overtreatment would be advisable. One skin unit to individual lesions and observation for at least a month before repetition would be safe.

Freezing the lesion with carbon dioxide snow or, if this is not available, with dry ice is also very effective. In skilled hands the use of the fulgurating spark is highly satisfactory.

EFFECTS OF COSMETICS ON SKIN

To the Editor—Has any research work been done on face powder and rouge as regards its effect on the skin? A number of my patients have had trouble from cosmetics.

S CHASE TUCKER M D Peabody Mass

ANSWER—Most of the investigative work on the effects of face powder and rouge on the skin has been done in the field of allergy. Certain powders, no matter how pure and mild in their effects on most skins produce an untoward reaction in the person whose skin is susceptible to irritation from one or more ingredients in the powder. Certain ingredients are more or less allergenic. Among them may be mentioned metallic substances such as white lead, bismuth, mercury, a zinc compound, also aniline dyes and some perfumes. Heliotropin and orris root seem to be the more irritating of the perfume preparations. Powders containing starches, calcium carbonate, gypsum and barium sulfate may be irritating. Orris root was a great offender many years ago but is rarely used in modern

powder manufacturing. Poucher reports zinc stearate and zinc oxide as irritating elements to the skin. Face powders should be free from gritty, sharp particles and all impurities. Rouges should contain no irritating dyes. Some women are sensitive to colors derived from eosin.

One of the most important elements in preventing irritation from face powders is the matter of thorough cleansing at bedtime. This is best done with a cleansing cream followed by soap and water. Leaving the powder in the pores without thorough cleansing is apt to produce inflammation or irritation which will not occur if the powder is removed properly.

INTERMENSTRUAL DISCHARGE

To the Editor—A white woman, aged 29 until about nineteen months ago had a normal menstrual period occurring every twenty eight days and lasting five or six days. Nineteen months ago he had an induced abortion with no complications. Since that time she has had a black discharge beginning several days before the regular menstrual period. This has increased until for the past four or five months it has begun exactly two weeks before the regular day of onset of the menstrual period occurring on any straining and especially during coitus. This flow is not constant during the two weeks and is of small amount. The amount increases during coitus. There is no pain during this time but the patient is nervous and at times has a temperature around 99.8 F. The regular menstrual period still occurs every twenty eight days but lasts only three or possibly four days. The flow is fairly normal during this time. The cervix is apparently normal. I would appreciate any suggestions you have to offer in this case.

M D Texas

ANSWER—It is possible, although not highly probable, that there may be a small placental mass in the uterus. Nearly always, however, when such tissue is present, there is more or less persistent bleeding and not periodic bleeding such as in this case. A more likely cause for the abnormal bleeding is the condition known as mittelschmerz, or intermenstrual pain. In typical instances of this kind, pain low down on one side of the abdomen occurs in the midperiod between flows. This pain may recur on the same or the opposite side. In some cases bleeding accompanies the pain and in other instances there is intermenstrual bleeding and no pain. The cause of the pain and the bleeding is ovulation. Usually no treatment need be instituted in these cases, especially because there is no satisfactory way to stop the pain or the bleeding. When the pain is severe, however, drugs must be prescribed. Since in this case the disturbance did not begin until an induced abortion was performed, because the flow lasts almost two weeks and because the patient has an elevated temperature during the time of the abnormal flow it is advisable to perform a curettement in the hope that a local cause may be found and removed. This should preferably be done when the patient does not have fever, namely, in the first half of the intermenstrual period.

CHROMIUM IN DRINKING WATER

To the Editor—Recently one of our county health commissioners directed attention to a proprietary preparation which was being added to the water supply of a school for the purpose of preventing corrosion of piping. Examination of the product indicated that it was a solution of sodium silicate and a chromate. The laboratories reported the specific gravity to be 1.41, total solids 63.6 Gm per hundred cubic centimeters, silica SiO₂ 29 per cent by weight, chromium in terms of sodium chromate Na₂CrO₄ 0.44 per cent by weight. The distributors of this product state that their prescribed dosage is 1 quart to 5,000 gallons of water. This is equivalent to 0.31 part per million of sodium chromate Na₂CrO₄ or to 0.10 part per million of chromium Cr. It is understood that it is added either to the cold water supply or to the hot water supply or to both. Information at hand indicates that several schools and certain commercial interests have been using the product and that its use may tend to extend. I have been unable to locate any reference as to the effect of drinking water containing small amounts of chromium and would greatly appreciate your opinion as to whether you would consider either the intermittent or the continued drinking of water containing chromium to the extent of 0.3 part per million of sodium chromate might have any harmful physiologic effect, and what limit should be set for the chromium content of drinking water.

WALTER H. HARTUNG M D Columbus Ohio

ANSWER—Chromate as here applied represents hexavalent chromium, but in the presence of water with any appreciable organic content and after a considerable interval of time, represented by hours, this hexavalent chromium may be changed over to a trivalent compound. Trivalent chromium is substantially nontoxic but the hexavalent compounds are much more toxic. The presence of excess chlorine in a water supply tends to inhibit the chemical change mentioned. Moreover since the query refers to a school water supply the implication is that the elapsed time between chromium water treatment and water use might be much less than is true for a large city. In the case of inhaled chromates the upper limit of safety for extended exposures is somewhat arbitrarily fixed at 1 mg of chromates to 10 cubic meters of air, the latter figure approximating the quantity of air breathed by an adult during a work day. Under

the circumstances mentioned it appears that if a gallon of water should be consumed daily, approximately 1 mg of the chromate would be ingested. Probably this quantity would lead to no demonstrable physiologic abnormalities, but an unequivocal stand may not be taken.

At this time, compounds containing chromium are regarded as sensitizing agents. It is conceivable that chromium in small quantities might lead to dysfunction because of sensitization. It is more likely under other circumstances that workers sensitized through greater exposure connected with employment might respond through allergic manifestations to the minute traces mentioned, following ingestion or even in connection with bathing. It is the intent of this discussion not to condemn the practice mentioned in the query as wholly unwarranted but to point out the possibility of ill effects.

FATAL METHYL SALICYLATE POISONING

To the Editor—A white girl aged 15 months was first seen half an hour after ingestion of approximately 1 ounce (30 cc) of oil of wintergreen. The taking of the fluid was accidental the wintergreen having been used to rub on arthritic joints of an older person in the household. According to the family the child had vomited twice and the vomiting was followed by one convulsion before I was called. When I arrived, the child had cyanosis of both hands and feet but the face and head were pink. The child was in a coma. Since its jaws were so spastic that they could not be opened enough to introduce a small stomach tube, the child was given one fourth grain (0.016 Gm) of codeine and was rushed to the hospital immediately. The jaws were then tried open by a mouth gag and a small stomach tube was introduced and the stomach lavaged with a solution of sodium bicarbonate. The child never regained consciousness but had two more convulsions and died. I have been unable to find reports of such cases in the literature. Is this poisoning of frequent occurrence? Since oil of wintergreen is commonly used should not this form of poisoning be given more attention in the medical literature?

W L SHARP MD Anderson Ind

ANSWER—The oil of wintergreen was probably methyl salicylate, which is prepared synthetically and is official in the United States Pharmacopeia with a dose of 0.75 cc.

While fatal poisoning with methyl salicylate is not frequent, cases have been reported in which death resulted from the ingestion of 30 cc by an adult. Others report severe poisoning from 30 cc but with ultimate recovery. The usual symptoms are severe abdominal pain, vomiting, convulsions, coma and suppression of the urine. More frequently the use of methyl salicylate as an internal therapeutic agent to replace the other salicylates has been followed by gastric distress with abdominal cramps and evidence of kidney irritation.

Since methyl salicylate has caused death in relatively small amounts, and even in therapeutic amounts may give rise to severe intoxication, its use should be restricted to external applications and its internal use discouraged.

DIMPLING OF FINGERS IN DEHYDRATION

To the Editor—Is dimpling of the anterior surface of the finger tips as a sign that dehydration is becoming dangerous worth adding to the innumerable signs? I have had occasion to note this sign for some thirty five years. I do not see it mentioned in French's book of differential diagnostic signs and symptoms. H B AITRENS MD Le Center Minn

ANSWER—Dehydration is always potentially dangerous. The sign mentioned is seen only in severe and precarious dehydration. It would be most unwise to rely on and wait for such dimpling of the skin before taking measures to combat dehydration, there are many other earlier and readily observable phenomena giving warning of inadequate fluid retention.

GASTRIC FISTULA AFTER REPAIR OF PERFORATED ULCER

To the Editor—In a case in which a large indurated and perforated gastric ulcer on the posterior wall of the lower third of the stomach is repaired without a gastro-enterostomy and a week later a gastric fistula develops what are the chances of this closing without a secondary operation? What medical treatment would be indicated? MD Minnetota

ANSWER—A fistula following closure of a perforated gastric ulcer will almost invariably heal without further operation. The only deterrents are an unrecognized carcinomatous ulcer and occasionally a high grade obstruction resulting either from the closure or from spasm. The medical treatment indicated naturally includes the control of gastric acidity. This can be done in several ways. A Levine tube may be introduced into the jejunum for feeding and nothing given by mouth for a number of days. This gives the stomach complete rest and gastric secretion usually ceases during the starvation period. Another method is to put the patient on regular ulcer management seeing that the acidity is completely controlled either with

milk and cream or with milk and cream plus alkalis such as calcium carbonate, calcium phosphate or calcined magnesium. Erosion of the skin of the abdominal wall from the action of the stomach juices has frequently been bothersome, although not the serious problem encountered in duodenal fistulas. To overcome this erosion, a number of devices have recently been suggested, such as the local application of a liquid rubber solution dusting the area with fullers' earth, or the use of proteins like beef broth.

DANGERS FROM ARSENIC IN PSORIASIS

To the Editor—In a case of psoriasis involving the entire scalp and large areas on the body and extremities under treatment with solution of potassium arsenite the psoriatic lesions disappeared almost completely leaving but two or three small patches not greater than a centimeter on the body. Treatment was discontinued because of the toxic manifestations of the drug. The dermatitis reappeared in about four weeks and was cleared up again in about three weeks with the use of the same arsenical preparation. It has now been six or eight weeks since the dermatitis was cleared up for the second time and again it seems to be reappearing extensively. I should like to know whether it would be safe for me to resort to the same medication in the treatment of this condition and whether its long continued use would lead to severe if not permanent damage to the parenchyma of such organs as the liver and kidneys.

D P SCHULTZ MD Port Jervis, N Y

ANSWER—Long continued use of arsenic will lead to damage sooner or later, even if nothing more than pigmented areas on the skin and hyperkeratoses. A rest of at least six months should be given between courses of arsenic.

CONGENITAL SYPHILIS

To the Editor—A premature infant of seven months gestation weighing 3 pounds 4 ounces (1475 Gm) with a four plus cord Wassermann reaction has survived nine days with no clinical symptoms of syphilis. His mother was not aware that she had syphilis. At a premarital check up a year ago both parents had negative blood Wassermann reactions. How soon should this infant begin having antisyphilitic treatment? His present weight is 3 pounds 1 ounce (1390 Gm) and he is taking his feedings well by gavage. What drugs would be best in this case? MD California

ANSWER—If the baby has congenital syphilis the mother has syphilis. The disease in the mother can usually be determined by a sensitive, properly done blood Wassermann or Kahn test. This should be done. If the baby has congenital syphilis, roentgenograms of the long bones will usually reveal pathognomonic evidences of the disease. A strongly positive cord Wassermann reaction probably means congenital syphilis in the large majority of instances. However, it seems to be generally agreed that antisyphilitic treatment should not be begun on such evidence alone. If the baby has congenital syphilis its blood will soon give a positive Wassermann or Kahn reaction. The test should be repeated certainly every two weeks until a positive reaction is obtained or until the baby is 4 months of age.

Treatment should be instituted as soon as the diagnosis is made. Sulfarsphenamine can be used, about 10 mg per kilogram of body weight, and slowly increased to 20 mg. It is important not to use large doses of either arsenic or bismuth compounds at the start. Bismuth compounds should be used in appropriate doses and in courses alternating with the arsenic. What is probably more important than particular drugs or dosage is that the treatment be continuous.

ACRIFLAVINE IN LETHARGIC ENCEPHALITIS

To the Editor—What is the opinion of the medical profession on acriflavine in lethargic encephalitis? The patient has been sick for fourteen months and little or no change has been noticed during the last six. Food and drugs are taken by mouth and there seems to be no further loss of weight. Any suggestions will be appreciated. MD Kentucky

ANSWER—Acriflavine is a dye which has been used in a few acute cases with alleged benefit. Little or no benefit has been reported in later cases. In the reliable reports by the Matheson commission (1932) one reads "The recommendations for acriflavine are apparently based on opinions rather than results."

PNEUMOPERITONEUM IN PULMONARY TUBERCULOSIS

To the Editor—Please tell me where to cure some detailed information on the technique of giving pneumoperitoneum in the treatment of pulmonary tuberculosis. ROBERT A STAFF MD Richmond Va

ANSWER—The technique, indications and dangers of pneumoperitoneum have been discussed in the following articles:

Vadja L. *Zitel's Tuberc* 67:371 (1933)
Panyai A. L. *Am J Tuberc* 29:603 (June) 1934
Trimble H. G. and Wardrip I. H. *ibid* 30:111 (July) 1935
Fremmel Frank *ibid* 30:444 (Oct) 1935

Genital Abnormalities Hermaphroditism and Related Adrenal Diseases By Hugh Hampton Young M A M D Sc D Professor of Urology the Johns Hopkins University Baltimore Cloth Price \$10 Pp 649 with 534 illustrations by William P Didusch Baltimore Williams & Wilkins Company 1937

This volume marks an important milestone in medical literature The interest of its content extends far beyond the realm of urologic and gynecologic surgery and impinges forcibly on the spheres of the internist, the psychiatrist and the pediatrician as well as on those of the urologist and the gynecologist Nothing of its kind has appeared before and the book is destined to be a standard for many years Dr Young has had the rare opportunity of having access to a huge clinical material and has shown the same genius for pioneering in the correction of congenital abnormalities that he has demonstrated in his earlier publications

The first seven and ninth chapters are devoted to a discussion of hermaphroditism and pseudohermaphroditism and occupy approximately 200 pages The discussion is inclusive and takes up the subject from the classical period of Greek art to the most recent contributions on the embryology of the condition The intersexes are described Dr Young has simplified for practical purposes the complex Latin terminology pertaining to pseudohermaphroditism and has adopted the following plan "If the gonads are testes, the patient is called a male pseudohermaphrodite, if ovaries, a female pseudohermaphrodite" The detailed case reports of a series of pseudohermaphrodites and the beautifully illustrated operative technics for their surgical correction are shown in the clear drawings of Mr Didusch Almost every conceivable aberration from the normal has come under the observation of Dr Young and he has made life bearable for many of these unfortunate persons by the remarkable reconstructive surgery illustrated

The eighth chapter discusses the adrenogenital syndrome and its intimate relationship to pathologic changes in the adrenal cortex Most of the cases have been observed in females The operation for the simultaneous exposure and study of the adrenals is a distinct contribution to this branch of surgery, because up to the present all technics other than actual inspection of both adrenals have proved often unsatisfactory and occasionally deceptive

The vaginal abnormalities in hermaphroditism and their correction are discussed in the ninth chapter The plastic corrective surgery on the female genitalia as illustrated in this chapter again demonstrates the peculiar aptitude of the author for this highly specialized type of surgery Masculinization due to ovarian tumors is next described and is illustrated by cases of arrhenoblastoma The tenth chapter deals with the prostate gland in females Its relation to hyperplasia of the adrenal cortex according to Young seems conclusively proved Concomitant effects of adrenal cortical hyperplasia are noted, hypoplasia of the ovaries, failure of the vagina to descend normally, a continuation of the growth of the phallus and the continued growth of the prostatic ducts in the female to form a small but definite prostate as well as other signs of virilism Hypergenitalism in boys and girls is next described at length, ascribed to various endocrinopathies Hypogenitalism and gynecomastia are adequately discussed

The next six chapters are devoted to the congenital abnormalities of the genito urinary tract which the average surgeon is more frequently called on to correct, while of the same high standard as the preceding fifteen chapters, they are not as striking in their content because of our greater familiarity with them The concluding chapter on the relation of the genital tract to the endocrine glands, is a complete summary of present knowledge concerning this fascinating complex, and ever changing subject

As a whole, this volume is a well rounded work on the subjects discussed and should be read by every physician concerned with the aberrations in the physical and mental makeup of human beings

Differentialdiagnose in der Inneren Medizin Von Prof Dr med O Naegeli Gew Direktor der Medizinischen Universitätsklinik Zürich Lieferung 3 Paper Price 10 80 marks Pp 415 772 with 59 illustrations Leipzig Georg Thieme 1937

The third volume of Naegeli's differential diagnosis continues the high quality of condensed discussion observed in the previous two volumes (reviewed in *THE JOURNAL* July 11, 1936, and April 3, 1937). The present volume includes presentation of the problems of differential diagnosis in the febrile diseases, diseases of the bones and joints, diseases of the esophagus, diseases of the heart and blood vessels, diseases of the kidneys and urinary tract, diseases of the nervous system and, in a small section, endocrine disorders. It is curious that diseases of the esophagus are included in this volume the second volume contained discussion of all other parts of the gastro intestinal tract. The discussion of cardiac diseases is good although tremendously condensed. The discussion of the differential diagnosis of the nephritides is the poorest section of this volume. Here as in the previous volumes one gains the impression that the patient is considered as a loosely correlated collection of systems rather than as a finely equilibrated whole. The printing and paper are good but the binding is atrocious, before three pages had been read the paper binding split and pages began to fall out. Cheaper binding and printing of medical works, so that frequent revisions can be made without too much expense to the readers, are highly desirable, but there are limits which should not be passed. A book should at least stand the handling of one reading. This series of volumes can be recommended as reference work revealing the modern German thought and methods in diagnosis.

Demonstrations of Physical Signs in Clinical Surgery By Hamilton Bailey FRCS Surgeon Royal Northern Hospital London Sixth edition Cloth Price \$6 50 Pp 284 with 358 illustrations Baltimore William Wood & Company 1937

The appearance of the sixth edition of this work within ten years is indicative of its popularity and usefulness. As its name suggests, it is not a textbook of surgical diagnosis. It deals essentially with various clinical signs in surgery, how they can be elicited and their significance in establishing a diagnosis. The book is profusely illustrated with clearly reproduced photographs, diagrams and colored plates which greatly enhance the descriptions and teaching value of the text. This volume, written in the usual clear simple style of the author, can be easily used and understood even by the beginner.

Le système nerveux végétatif Par J Tinel Paper Price 160 francs Pp 847 with 306 illustrations Paris Masson & Cie 1937

The first part of this book deals largely with structure. In his description of the anatomy the author places great emphasis on the autonomous interstitial plexuses and cells of the viscera. His discussion of the sympathetic and parasympathetic systems follows accepted lines. The histology of the vegetative system is described in some detail with beautiful illustrations. Many of the photographs, however, seem to have been extensively retouched. Chapter 2 contains a useful summary of recent work on hormonal and pharmacologic substances activating or paralyzing the vegetative nervous system. In chapters 3 and 4 the sympathetic and parasympathetic systems are described in detail and the functions of their various fibers discussed. The second part of the book deals with the vegetative functions—pilomotor secretory, vasomotor sensory and trophic—and ends with a discussion of the superior vegetative centers and their influence on the regulation of heat sleep, psychic functions and the metabolism of water and fat. The description of the pilomotor system follows the classic researches of Andre Thomas. The author accepts the general view at the present time that the sympathetic system exercises no direct action on the tonus or contraction of striated muscle. The recent researches of Fulton and his associates on the cortical representation of the vegetative system are not mentioned. The third part of the book discusses the clinical syndromes resulting from lesions at various points of the vegetative nervous system both central and peripheral. In the section on sympathetic reflex pain a great number of clinical histories are introduced and it would make an interesting appendix to the recent volume of Leriche

on the surgery of pain. The author warns that any attempt to suppress by surgical means a pain of sympathetic origin must radically and at once remove the causal local irritation or the trouble will be made much worse. His discussion of surgical intervention contains but little with regard to technique, being concerned mainly with principles. The book ends with a discussion of medical and physical therapy. The personal touch is most evident in the sections dealing with the reflex vasomotor and painful syndromes. The rest is mainly a compilation from the literature, albeit a useful one especially for its summary of French work often difficult to obtain.

Operative Surgery By J Shelton Horsley MD LL.D F.R.C.S. Attending Surgeon St Elizabeth's Hospital Richmond Va and Isaac A Bigger MD Professor of Surgery Medical College of Virginia Richmond Va. With contributions by C C Coleman MD F.R.C.S. Professor of Neurological Surgery Medical College of Virginia John S Horsley Jr MD Assistant Professor of Surgery Medical College of Virginia Austin I Dodson MD F.R.C.S. Professor of Urology Medical College of Virginia and Donald W Fullmer MD Associate Orthopedist Medical College of Virginia Volumes I and II Fourth edition Cloth Price \$15 per set Pp 674 675 1347 with 1209 illustrations by Miss Helen Lorraine St Louis C V Mosby Company 1937

This is one of the most salutary and serviceable contributions to the literature on operative surgery that has appeared since "The Text Book on Operative Surgery" by Theodore Kocher in 1911. Whether or not one agrees with the various hypotheses suggested throughout the text as a means of explaining some of the more obscure and recondite biologic reactions following many different surgical procedures one cannot but admire and regard with the deepest interest the constant repetition of the suggestion and thought that the art of operating combined with a thorough knowledge of anatomy, while essential, must never blind the surgeon to or allow him to be unmindful of the correct physiologic principles involved and the consequent biologic effects of a surgical operation. The student of surgery is importuned constantly to recall that 'real progress in surgery lies not so much in cultivating the art of surgery and in striving after mechanical dexterity, which is important but can be acquired in a few years, as in the study of biological principles that concern function, nutrition, metabolism and repair of tissue and in the thoughtful application of these principles to every operation and to every method of surgical treatment'. This plea to the student to regard surgery in this broader aspect is stimulating and immediately distinguishes this treatise from other operative surgeries which while perhaps more inclusive have been mere technical encyclopedias. The large personal experience of Dr Horsley senior and his distinguished collaborators has been related in an attractive and readable manner. The format of the books is excellent. It might be said without exaggeration that this is the only operative surgery published in recent years in which there has been any evidence whatever of the student in it. A sense of selective appraisal pervades the entire text, the authors making no attempt to be inclusive. The surgical policy and philosophy based on the large clinical and experimental knowledge of this distinguished group of surgeons from one of the more prominent medical centers has been annotated. It is not only a pleasure to read but a real help on 'the night before' when sitting in one's study planning an operation for the following morning. The simple concise description of technical procedures experienced by the author, together with their opinions and their suggestions as to the relative merits of special operations described by others reveals pertinent thought and mature judgment. There has been no 'stuffing' of the text for the sake of forming an impressive but as a rule, totally useless cumbersome index and bibliography. At the conclusion of each chapter a succinct relevant bibliography is given that provides a ready index to a more detailed literature pertaining to any one subject. It is of course obvious that accessibility and brevity must run hand in hand in any textbook on surgery when one considers the great volume of literature that must be digested and that cannot be presented in detail. The illustrations are excellent and remarkably clear. In some instances where they have been redrawn from the original papers the copies are clearer and more descriptive than the original drawing. Every operating surgeon and medical student as well as those in surgical research should have the volumes right at hand on their book shelves.

Die Irradiation autonomer Reflexe Untersuchungen zur Funktion des autonomen Nervensystems By Dr Alfred Schwelzer Assistant in Department of Physiology Middlesex Hospital Medical School University of London Paper Price 40 Swiss francs Pp 376 with 38 illustrations Basel S Karger 1937

This textbook on the autonomic nervous system is modern, complete and critically written. The subject matter is described clearly. After two chapters on introduction and classification of the subject matter, the book is divided into three large chapters. The first deals with a general discussion of the conception of nervous irradiation, autonomic reflexes anatomic groundwork and irradiation of the autonomic reflexes, followed by a summary and conclusions. The second chapter deals with a special discussion of the skin and sensory nerves, eye and eye ball, the ear, the respiratory apparatus, the digestive system, the urogenital structures and finally the blood vascular system. The last chapter discusses the biologic significance of the autonomic reflexes. There is an unusually good bibliography occupying about forty printed pages. It includes all the investigators in the field of the autonomic nervous system. There is a general index and an index of authors.

Primary Carcinoma of the Lung By Edwin J Simons MD Member of the Staff St Gabriel's Hospital Little Falls Minnesota Cloth Price \$3 Pp 263 with 31 illustrations Chicago Year Book Publishers Inc 1937

This is a good review of the present knowledge of carcinoma of the lung. The writer has assembled the more important publications on the subject and added a few cases of his own. The author devotes thirty pages to the incidence of primary carcinoma of the lung, with the conclusion that the disease has increased both absolutely and relatively. The etiology of cancer of the lung is discussed in forty pages. The majority of workers have found no single etiologic agent but numerous forms of chronic irritation which cause epithelial metaplasia and malignant conditions. There are thirty pages on pathology. The histologic types are divided into (1) adenocarcinoma (2) squamous cell and (3) undifferentiated round and spindle cell, in accordance with the important contribution of Arkin and Wagner in *THE JOURNAL*, Feb 22, 1936. The table of these two authors is reproduced, giving the histologic type and site of metastases in seventy-four cases examined post mortem. The clinical considerations cover seventy pages. Sex age incidence, clinical classification, symptoms, physical appearances and laboratory data are summarized. The value of the x-rays and bronchoscope are emphasized. The dictum of Arkin and Wagner that "a peculiarly characteristic history of pulmonary well being to within an average of eight months before seeking medical aid, the development of bronchitis or recurrent attacks of pneumonia or pleurisy, persistent cough, pulmonary or extrapulmonary pain, hemoptysis and dyspnea should enable the physician to suspect pulmonary cancer" is reaffirmed by the author's review of the literature. The subject of therapy is discussed with special reference to surgical removal in early cases. The book closes with a bibliography of twenty pages. This book should convince those physicians who are still skeptical about the frequency of primary pulmonary cancer that the disease constitutes about 7 per cent of all primary malignant growths. The only hope of cure is surgical removal in early cases before metastases have spread to other organs.

The Practitioners Library of Medicine and Surgery Volume XIII Supplement—Index Supervising Editor George Blumer M A MD David P Smith Clinical Professor of Medicine Yale University School of Medicine Cloth Price \$10 Pp 1161 with illustrations New York & London D Appleton Century Company Incorporated 1938

This volume completes the extensive work which has been engaging Dr George Blumer and his associates for some years. In this supplementary volume a variety of subjects are concerned the main headings having to do with endocrinology, medical technic, infectious diseases, diseases of metabolism, of the gastrointestinal tract, of the lungs and of the heart, obscure diseases, therapeutics, anesthesia, genito-urinary system, and the psychologic aspects of pediatric practice. Presumably some of the essays arrived too late to be included in the volumes into which they might have fitted better. It is useful however, to have all of them available for the system would have suffered by their absence. This volume also contains the complete index, which occupies about 350 pages.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Health Insurance "Disease of Organs Which Are Not Common to Both Sexes" Construed—The defendant insurance company insured the plaintiff against loss of time on account of disease, with the proviso that the policy was not to cover death or disability from any "disease of organs which are not common to both sexes." The insured contracted gonorrhea that resulted in a prostatic abscess and bilateral epididymitis. The company refused to pay the benefits provided in the policy, and the plaintiff sued and obtained judgment in the trial court. The defendant then appealed to the Supreme Court of Nebraska.

A health and accident insurance company, said the court, may limit its liability in any reasonable manner and it may therefore exclude liability for diseases of organs not common to both sexes. Such an exemption, in the opinion of the court, would create an impression on a male layman that it was intended to exempt gonorrhea from the coverage of the policy, although it did not specify that disease. Such an insured would naturally consider that any disease which would afflict him through his penis and its adjuncts would be exempt under the policy because the same disease would begin its course in a female through her genital organs, which he would well understand were not "common" with his, though they have some of the functions similar or complementary to his. The general understanding of the lay mind, the court thought, is that the male and female genital organs are "not common to both sexes." That both sexes have a urethra, both have a bladder and both have a blood stream, all of which may be ultimately affected, does not make the organs of the plaintiff which were primarily affected by the gonococci, and the genital organs of a female "common to both sexes." The Supreme Court, therefore, reversed the judgment of the trial court for the plaintiff and directed that court to enter a judgment for the defendant.—*Hamilton v Mutual Ben Health & Accident Assn (Neb)*, 275 N W 863.

Workmen's Compensation Acts Detachment of Retina Attributed to Trauma—Attributing the detachment of the retina of his left eye to a blow received during the course of his employment, the plaintiff instituted proceedings under the workmen's compensation act of Nebraska. The trial court awarded compensation and the defendant employer appealed to the Supreme Court of Nebraska.

In May 1933 the plaintiff while working on a farm was injured by a piece of steel entering his left eye. Attempts made by a physician to remove the steel splinter were unsuccessful. The removal of the eye was recommended but the plaintiff refused to submit to the operation. Apparently the eye improved and the plaintiff subsequently began work for the defendant. According to the plaintiff's testimony, on Sept 2 1935 while in the performance of his work, he bumped his head on a piece of pipe. Five days later he went to a hospital for an operation on his left eye. The attending physician diagnosed the trouble as a retinal detachment which the plaintiff contended was due to the blow he had received September 2.

The physician who attempted to remove the steel splinter in 1933 testified that he had at that time recommended the removal of the eye for the reason that complications were bound to come sooner or later which would seriously damage the uninjured eye. He also testified that the steel splinter was the cause of the detached retina and that the alleged trauma to the head was merely coincidental with the development of the condition resulting in the detachment of the retina. He further testified that the steel splinter was reduced in size during the two years it was embedded in the eye and that this breakdown of the foreign body would produce a low-grade inflammatory reaction in the retina which would ultimately cause a detach-

ment of it. Another physician, however, testified to the effect that the steel splinter would cause the plaintiff no harm after it became encysted, in the absence of trauma. He testified, further, that the plaintiff suffered from sinus infection in August 1935 that required a drainage of the sinuses by operative surgery. After the operation the sinuses cleared up, but the plaintiff's left eye was inflamed to such an extent that medical treatment was continued. This condition existed prior to the date of the alleged accident and continued until it was diagnosed on Sept. 4, 1935, as retinal detachment. The plaintiff offered in evidence quotations from medical books citing instances in which steel and copper foreign bodies had remained in the eye for many years and even for a lifetime. An examination of these authorities, however, convinced the court that they were cited as rare exceptions to the general rule that an eye containing a steel or copper splinter generally breaks down as a result thereof in a much less period of time.

For the plaintiff to be entitled to compensation, the court said, he must prove by preponderance of the evidence that he suffered an accident arising out of and in the course of his employment which resulted in the injuries for which he claims an award. This, the court said, the plaintiff failed to do. The only proof in the record that he suffered injury while in the employ of the defendant was the evidence he himself gave. His testimony that he was injured while working was impeached by the testimony of three other witnesses. The evidence, the court continued, indicated that the plaintiff had prior to the date of the alleged accident an inflammation of the left eye after the sinus infection had been relieved which continued until the trouble was diagnosed as a detachment of the retina. The fact that only the left eye was inflamed during this period was indicative of the commencement of the deterioration of the eye before the alleged accident occurred. That inflammation of an eye containing a steel particle is a sign of an impending retinal detachment seemed to the court to be sustained by the testimony and by the medical authorities cited.

Finding that the plaintiff had failed to prove by a preponderance of evidence that he suffered an injury arising out of and in the course of his employment, the judgment of the trial court granting compensation was reversed and the action dismissed.—*Loehr v. Alamito Dairy Co. (Neb.), 275 N. W. 596*

Telephone Liability for Failure to List Physician in Classified Section—The plaintiff, a physician, subscribed for a business telephone and the telephone company entered into a contract with him to list his name in both the regular and classified business sections of the telephone directory. The company contracted with the defendant publishers for the editing and publication of the telephone directory. The plaintiff's name did not appear in the classified section, he sued the telephone company and the publishers and the jury returned a verdict for \$3,000 for the plaintiff. The defendants filed separate motions for new trials and motions for judgment notwithstanding the verdict. The motions for a new trial were sustained but the motions for judgment notwithstanding the verdict were overruled. The defendants then appealed to the court of appeals of Ohio, Hamilton County.

There was clearly a contract between the plaintiff and the telephone company, the court said, for the listing of his name in the classified section. For a failure so to list, the plaintiff had a cause of action unless there were some circumstances which would excuse performance by the telephone company. The company argued that it complied with all legal requirements by listing the physician in the white section of the directory. But the court said, while the rules and regulations of the Public Utilities Commission required the listing only in the white section, this was the minimum requirement and did not in any way limit or prohibit the subscriber from making arrangements for the betterment of his service. There was nothing in such rules and regulations to prohibit or make illegal the carrying of names and numbers in the classified business section. Furthermore, continued the court, the contract between the telephone company and the publishers was one by which the latter undertook to perform a duty the telephone company owed the

plaintiff. The plaintiff, therefore, was a creditor beneficiary of that contract and as such could maintain an action against the publishers. The trial court did not err, said the appellate court in overruling the motions for judgment notwithstanding the verdict for the plaintiff.—*Tail v. Reuben H. Donnelly Corporation (Ohio), 10 N. E. (2d) 239*

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Prevalence of Trichinosis—From 2 597 cadaver examinations summarized from the literature since 1901 an incidence of trichina infestation of 12.3 per cent is derived. Scheffey discusses a survey of 118 cadavers from Minneapolis and St. Paul Charity hospitals of which 12.7 per cent were found to harbor the trichinae. This is combined with a previous report on 117 cadavers from the dissecting room from Minneapolis giving 23.5 cases with an incidence of 14.4 per cent. Evidence is presented which indicates that the incidence of trichinosis among the adults of the United States is about 20 per cent.

Clinical Observations on Use of Liver Fraction—

Barker and Miller administered orally the secondary anemia liver fraction of Whipple and his co-workers to eleven patients with chronic hypochromic microcytic anemia. During the control period eight patients showed at least a slight reticulocyte response to 70 mg of iron a day, which responses varied from 12 to 7 per cent and occurred between the fourth and the tenth day after the initial dose of iron. Following the peak, the reticulocyte curve declined or flattened out until 25 Gm of liver extract daily was substituted for the inorganic iron preparation in the second observation period. Then each of the eleven patients gave a secondary reticulocyte response to this liver fraction the peak of the rise ranging from 3 to 15.8 per cent. A moderate rise in levels of erythrocytes and hemoglobin occurred during these first two periods of therapy, however, the rate of improvement in blood levels was much more rapid in the third period when the patients were receiving large doses of inorganic iron. Of the seven cases in which reticulocytes were followed throughout the third period, tertiary reticulocyte rises which equaled or exceeded the primary and secondary responses developed in five. It appears likely that the liver fraction contains reticulocytogenic material apart from its iron content.

Pulmonary Involvement in Lymphosarcoma and Lymphatic Leukemia—Falconer and Leonard attempt to correlate the clinical, pathologic and x-ray observations showing pulmonary involvement. The figures for pulmonary incidence were lymphatic leukemia 30 per cent and lymphosarcoma 36 per cent. Previous observations in Hodgkin's disease showed 31 per cent. Interest is enhanced if one considers Hodgkin's disease an infection and the former two diseases neoplastic in nature. From the clinical x-ray and pathologic aspects the authors' studies with reference to pulmonary involvement in the three groups of diseases show a striking similarity. In the cases of Hodgkin's disease the time between onset and appearance of pulmonary symptoms varied from onset with pulmonary symptoms to eight years. In two patients pulmonary symptoms were primary. In five patients the time varied from two months to eight years. The length of life after onset of pulmonary involvement varied from twenty-two to fifty-one months. These figures, when compared with the corresponding figures for lymphatic leukemia and lymphosarcoma show that the cases of Hodgkin's disease apparently ran a more slowly progressive and chronic course. In the lymphatic leukemia group the duration of life was from two months to eleven years, eight patients living less than four years after onset of symptoms. In the lymphosarcoma series the figures for duration of life are from four months to four and one-half years, eight patients living less than four years after onset of symptoms. Pulmonary involvement in the majority of cases in both series tended to occur when the disease became widespread in the body. Once the parenchyma of

the lung becomes involved or pleural effusion supervenes, the outlook is poor. Patients with either disease vary greatly in their sensitivity to radiation, and for this reason it should always be used to the full limits of its possibilities.

Nature of Magnesium Tetany—In a study of the syndrome of magnesium tetany, Greenberg and Tufts obtained results similar to those of Kruse, Orent and McCollum. The incidence, time of onset and duration of peripheral vasodilatation and hyperirritability in magnesium deficient rats were found to be greatly affected by the degree of magnesium deficiency, the starting age of the rats and the dietary levels of calcium and vitamin G. The lesion concerned with the hyperirritability appears to be in the midbrain or pons. This localization is supported by an increased sensitivity of the deficient animals to the convulsant action of picrotoxin and the protective action of subanesthetic doses of a barbiturate (sodium amytal) against convulsions. Magnesium tetany differs from calcium tetany in that curare does not prevent the onset of convulsive seizures in this condition.

Tuberculous Tracheobronchitis—Warren and his associates review the types of lesions present in seventy-four patients with tracheobronchial tuberculosis found during the last twelve months. The ulcerative lesions fall into two types: the discrete ulcer and the granulating ulcer. The granulating type has occurred most commonly about the orifice of the main bronchus on the carina and in the lower portion of the trachea. Healed and ulcerating stenosing lesions have been observed. The healed

stenosis represents a healed ulcerative lesion in which the reparative process has partially or completely occluded the lumen. The ulcerostenosis represents a stage midway between the healed, cicatricial stenoses and the granulating ulcer. Tuberculoma or tuberculous granuloma has been observed in four patients. In three patients there was a diffuse hyperemia of the bronchial mucosa with moderate mucosal edema. There are no clearcut grounds for the assumption that this is a tuberculous lesion other than that in two patients the sputum was positive, although neither had a demonstrable lesion to account for the tubercle bacilli. Biopsies were performed in fourteen cases in which the lesion was large enough to obtain tissue safely for study. In four instances the lesions were tuberculomas and in ten were of the granulating ulcer type in which the growth of granulation tissue was great enough to obtain a bite. The specimens for biopsy obtained from the four patients in whom a tumor mass was present were all tuberculous granulomas. The remaining biopsies in cases in which a granulating ulcer was present showed tubercles in four of the ten cases. Up till now there has been no evidence that removing small pieces of tissue from these lesions has led to any untoward results. The danger of perforating the bronchial wall in these cases outweighs the value of the additional information obtained by biopsy. The authors are unable to render the rather severe prognosis which has been given heretofore. In the number of cases reviewed there have been six deaths. These have not been due to the tuberculous bronchial ulceration but to the severity of the parenchymal lesion. Bronchial ulceration may be in some instances a manifestation of poorly resisted disease, but this is not true in all cases. In some instances such lesions heal spontaneously, but, when they are treated early, healing occurs and leaves little or no trace, when the ulcer is old and deep stenosis has already begun to develop and this is an irreversible process. It seems better to err on the side of performing a bronchoscopic examination on a patient with a normal bronchus when the diagnosis is in doubt than to leave the ulcer untreated.

Lupus Erythematosus—Ludy and Corson say that the incidence of lupus erythematosus in Philadelphia shows a decided increase during the last few years. The possibility that metallic poisons produce similar changes must be considered. Hematoporphyrin was noted in many patients with acute lupus erythematosus. This substance acting as a photodynamic sensitizer, could readily account for dermal changes. Along with other danger signals hematoporphyrinuria may take its place as a deterrent to the use of gold compounds in treating lupus erythematosus. The authors propose that in a susceptible subject, with a streptococcal toxemia or a tuberculous pyogenic focus, ground the presence of a porphyrin substance in the blood stream may engender photosensitivity and cause lupus erythematosus to appear as a result of exposure to light. In some cases a metallic element acting as a catalyst may be responsible for producing the same result. In all cases in which chronic di-

cold characteristics appear later there may have been a stage at which porphyrin was present. Porphyrin cannot be detected in abnormal quantities in the stationary stage. The presence of lead in the skin of every patient with lupus erythematosus that has been examined with the spectroscope seems more than coincidental and encourages further investigation of this aspect of the disease.

Serologic Evidence of Syphilis in Malarial Patients—In June 1935 the committee on evaluation of serodiagnostic tests for syphilis first reported on the frequency of positive reactions among patients with malaria. In a study of 266 presumably unsyphilitic patients with malaria, Hazen and his collaborators obtained eighty-two positive (8 per cent) and fifty-one doubtful reports. Serologic examinations were repeated on forty-nine of the fifty-one donors who showed one or more positive reactions, with the result that there was a decrease of twenty-four in a total of eighty positive reports. Among sixty-eight specimens from eighteen white girls less than 10 years of age there were 132 per cent that were positive, the highest percentage in any age group except that from 60 to 69 years. Female subjects showed a higher percentage of positive results than did males. Such figures do not follow the usual trend of the prevalence of syphilis. There is a striking dissimilarity of positive reports for the different age groups. It seems safe to assume that malaria, like leprosy, can be the cause of positive serologic reactions to tests for syphilis. It is probable that more than one patient has been placed under treatment for syphilis when malaria was the cause of his positive serologic reaction.

Serum Proteins in Hyperthyroidism—Brown and Meeray studied the total serum proteins in twenty-four cases of hyperthyroidism (twenty three of diffuse toxic goiter and one of toxic nodular goiter). In all cases the initial basal metabolic rate

was +30 or above. Serum protein determinations were made preoperatively and mostly before any iodine was administered. Similar studies were made at intervals varying from three to twelve months after operation. In fourteen of the group the concentration of the serum proteins rose after operation in excess of the error of the method, in fifteen the preoperative level was below the accepted normal concentration. No relation was found between the preoperative serum protein levels and the duration of the symptoms of hyperthyroidism, and the same is true for the percentage increase of serum proteins after operation, with percentage weight gain. The mean increase in serum protein concentration was 13, 15 and 14 per cent in patients gaining up to 10, 20 and more than 20 per cent, respectively, of body weight following operation.

Circumscribed Hypertrophic Proctitis—Fansler and Anderson discuss an inflammatory condition of the rectum which they have termed "circumscribed hypertrophic proctitis." The condition has been seen occasionally for many years but has been dismissed as an intractable proctitis. The distinctive characteristics are as follows: 1 A circumscribed area of inflammation of varying severity frequently with hypertrophic change which may or may not involve the anal canal. The lesion extends upward for only 2 or 3 inches, where the area of inflammation changes abruptly to normal rectal mucosa. 2 The condition is extremely chronic in character, does not yield to the ordinary method of treatment and remains localized regardless of its duration. 3 Perirectal abscess and fistula are common complications. 4 Actual cauterization is the most successful method of treatment.

of myocardial changes, can be excluded. The electrocardiographic changes consisted of extrasystolic and other disturbances in the rhythm and in changes in the intermediate portion of the electrocardiogram. Animal experiments and clinical observations, often corroborated by necropsy, show that the electrocardiographic changes are of central origin. By irritation of the sympathetic centers of the paramedian central gray substance, disturbances in the cardiac rhythm and in the cardiac blood perfusion can be elicited by way of the long cardiac nerves as well as by way of the descending tracts and of the spinal parasympathetic. In patients with brain tumors but with normal hearts such centrally elicited disturbances in the cardiac activity may dominate the clinical picture.

Cevitamic Acid Content of Cerebrospinal Fluid—Mella and Klimo say that efforts to utilize deviations in the cevitamic acid content of the cerebrospinal fluid as a diagnostic aid in diseases of the central nervous system have failed. On the other hand, low cevitamic acid content of the cerebrospinal fluid is the manifestation of a C hypovitaminosis. The authors studied the cevitamic acid content of the cerebrospinal fluid in the course of an entire year to be able to estimate the influence exerted by the food during the different seasons. They made systematic studies for thirteen successive months in 277 cases. Some of the specimens of cerebrospinal fluid were from normal subjects and some were from patients with disorders of the central nervous system. Since in both groups the values were often low and normal values were often found in patients with severe disorders of the central nervous system, it was concluded that the detected values were of no diagnostic significance. However, there were seasonal fluctuations of the cevitamic acid content of the cerebrospinal fluid. The minimum was detected during the spring months, the maximum during the fall. The authors conclude that the cevitamic acid content of the cerebrospinal fluid is an important diagnostic aid in the diagnosis of hypovitaminosis.

Diabetes Mellitus and Blood Pressure—Donhoff and Szabo's observations on 420 patients with diabetes and on a large polyclinical material convinced them that there is no difference in the incidence of hypertension in diabetic persons and in those without this metabolic disorder. Moreover as regards insulin requirements and mortality, they found no difference between diabetic patients with or without hypertension.

Reinjection of Irradiated Blood—Litzner cites the method of autohemotherapy introduced by Havlicek which differs from ordinary autohemotherapy in that the blood is subjected to ultraviolet irradiation. The authors begin with from 6 to 8 cc of blood, to which is added about one tenth of that quantity of 3.8 per cent sodium citrate solution. The first time they irradiate the blood for one half minute and subsequently increase the time by one-half minute each time until a total of five minutes has been reached. Usually the injections were given two or three times weekly until from fourteen to eighteen injections had been reached, in other cases daily injections were given for eight days and after that injections were given twice each week. The mode of injection was always intramuscular. Improvement generally became noticeable after five or six injections. Noteworthy is the improvement in the general condition and in the analgesic action, especially in arthritis deformans. In chronic infectious rheumatism the injection of the patient's own irradiated blood is of no special value. However Havlicek's autohemotherapy was effective in acute or subacute articular rheumatism. Acute allergic diseases of the skin reacted promptly to the injections. In the conclusion he says that reinjection of irradiated blood involves no dangers and can be used with good results in some arthritic and allergic disorders.

Cardiac Hemoptysis—Guizetti and Dinkler say that it is not so well known that pulmonary hemorrhages may develop in severe cardiac pulmonary stasis without the presence of infarcts. They describe six cases of their own. Stasis in the lesser circulation with increase in pressure (usually on the basis of mitral stenosis) leads, in case of a strong, not decompensated right side of the heart, to diapedesis in the region of the alveolar or bronchial capillaries or where these pass into the venous pulmonary region. The hemorrhages appear probably simultaneously at several sites and assume a profuse character. The treatment of these pulmonary hemorrhages is of little avail. Sedatives and rest in bed should be employed. Blood transfusion is contraindicated. The authors resorted to venesection in order to relieve the pulmonary stasis. They advise against the use of digitalis, strophanthin and similar cardiac remedies.

Cardiac Rhythm Affected by Irritation of Oral Mucosa—Medvei and Ueberall report the case of a woman aged 62 who, following follicular tonsillitis, developed piercing pricks in the left side of the neck during the swallowing of food. The attacks lasted only a few seconds, then gradually subsided and remained absent for a year then recurred. Anesthetization of the pharyngeal mucosa produced cessation of the attack for a time. Later the attacks recurred whenever food touched the left palatine arch or the left pharyngeal wall. When pressure is applied on this region the patient feels pain in the left ear, becomes pale and loses consciousness, the head and eyeballs turn to the right, the pupillary reactions are abolished and bradycardia occurs, pulsation decreases and clonic spasms are noticeable. The attack lasts from sixty to ninety seconds. Electrocardiographic studies revealed disturbances in the cardiac rhythm. During some of the attacks a nodal rhythm could be observed. The authors think that the disturbance in the cardiac rhythm and the accompanying loss of consciousness are doubtless of neurogenic origin and that they are elicited by way of the vagus nerve. The patient had a primary impairment of the cardiac muscle and a hypertension. Radium irradiation of the oral and pharyngeal mucosa stopped the attacks.

Treatment of Hemangiomas by Means of Borderline Rays—Dethmers decided to apply from 800 to 1000 roentgens per application and 8000 roentgens in all at intervals of six weeks. The current strength was 20 milliamperes, the tension 10 kilovolts and the focus skin distance 10 cm. He employed this form of borderline treatment in sixty-one cases of hemangioma of which twenty were cases of naevus flammeus and forty-one were tuberous hemangiomas. He gained the impression that the dosage was in some instances too small for naevus flammeus, but it was adequate for tuberous hemangiomas. The location seemed to be of no importance in tuberous hemangioma but in naevus flammeus a localization on the face had a less favorable prognosis than on other parts of the body. The possibility of obliteration by pressure indicates a favorable prognosis in case of naevus as well as of tuberous hemangiomas. The age of the patient is important in that the prognosis becomes more unfavorable with increasing age. About 50 per cent of the cases of naevus flammeus which are so feared for their refractory character, respond to the described treatment by means of borderline rays.
